ABSTRACT

A cubic graph G is *cyclically 5-connected* if G is simple, 3-connected, has at least 10 vertices and for every set F of edges of size at most four, at most one component of $G \setminus F$ contains circuits. We prove that if G and H are cyclically 5-connected cubic graphs and H topologically contains G , then either G and H are isomorphic, or (modulo well-described exceptions) there exists a cyclically 5-connected cubic graph G' such that H topologically contains G' and G' is obtained from G in one of the following two ways. Either G' is obtained from G by subdividing two distinct edges of G and joining the two new vertices by an edge, or G' is obtained from G by subdividing each edge of a circuit of length five and joining the new vertices by a matching to a new circuit of length five disjoint from G in such a way that the cyclic orders of the two circuits agree. We prove a companion result, where by slightly increasing the connectivity of H we are able to eliminate the second construction. We also prove versions of both of these results when G is almost cyclically 5-connected in the sense that it satisfies the definition except for 4-edge cuts such that one side is a circuit of length four. In this case G' is required to be almost cyclically 5-connected and to have fewer circuits of length four than G . In particular, if G has at most one circuit of length four, then G' is required to be cyclically 5-connected. However, in this more general setting the operations describing the possible graphs G' are more complicated.

1. INTRODUCTION

The primary motivation for this work comes from Tutte’s 3–edge-coloring conjecture [13], the following (definitions are given later).

(1.1) Conjecture. *Every 2–edge-connected cubic graph that does not topologically contain the Petersen graph is 3–edge-colorable.*

Our strategy is to reduce (1.1) to “apex” and “doublecross” graphs, two classes of graphs that are close to planar graphs, and then modify our proof of the Four Color Theorem [8] to show that graphs belonging to those classes satisfy (1.1). We began the first part of this program in [10], but in order to complete it we need to understand the structure of reasonably well-connected cubic graphs that do not topologically contain the Petersen graph. That is the subject of [11], where we apply the structure theory of cyclically 5-connected cubic graphs developed in this paper. We have completed the second part of the project for doublecross graphs in [5]; the apex case is harder and is currently under preparation.

To motivate our structure theorems let us mention a special case of a theorem of Tutte [12].

(1.2) *Let G, H be non-isomorphic 3–connected cubic graphs, and let H contain G topologically. Then there exists a cubic graph G' obtained from G by subdividing two distinct edges of G and joining the new vertices by an edge in such a way such that H topologically contains G' .*

Our objective is to prove a similar theorem for cyclically 5-connected cubic graphs. An ideal analog of (1.2) for cyclically 5-connected cubic graphs would assert that there is a graph G' as in (1.2) that is cyclically 5-connected. That is unfortunately not true, but the exceptions can be conveniently described. We will do so now.

Let G be a cyclically 5-connected cubic graph. Let e, f be distinct edges of G with no common end and such that no edge of G is adjacent to both e and f , and let G' be obtained from G by subdividing e and f and joining the new vertices by an edge. We say that G' is a *handle expansion* of G . We show in (2.2) that G' is cyclically 5-connected. Let e_1, e_2, e_3, e_4, e_5 (in order) be the edges of a circuit of G of length five. Let us subdivide

e_i by a new vertex v_i , add a circuit (disjoint from G) with vertices u_1, u_2, u_3, u_4, u_5 (in order), and for $i = 1, 2, \dots, 5$ let us add an edge joining u_i and v_i to form a graph G'' . In these circumstances we say that G'' is a *circuit expansion* of G . It is not hard to see, for instance by repeatedly applying (2.1), that G'' is cyclically 5-connected.

Let p be an integer such that $p \geq 5$ if p is odd and $p \geq 10$ if p is even. Let G be a cubic graph with vertex-set $\{u_0, u_1, \dots, u_{p-1}, v_0, v_1, \dots, v_{p-1}\}$ such that for $i = 0, 1, \dots, p-1$, u_i has neighbors u_{i-1}, u_{i+1} and v_i , and v_i has neighbors u_i, v_{i-2} and v_{i+2} , where the index arithmetic is taken modulo p (see Figure 1). We say that G is a *biladder* on $2p$ vertices. We remark that the Petersen graph is a biladder on 10 vertices, and that the Dodecahedron is a biladder on 20 vertices.

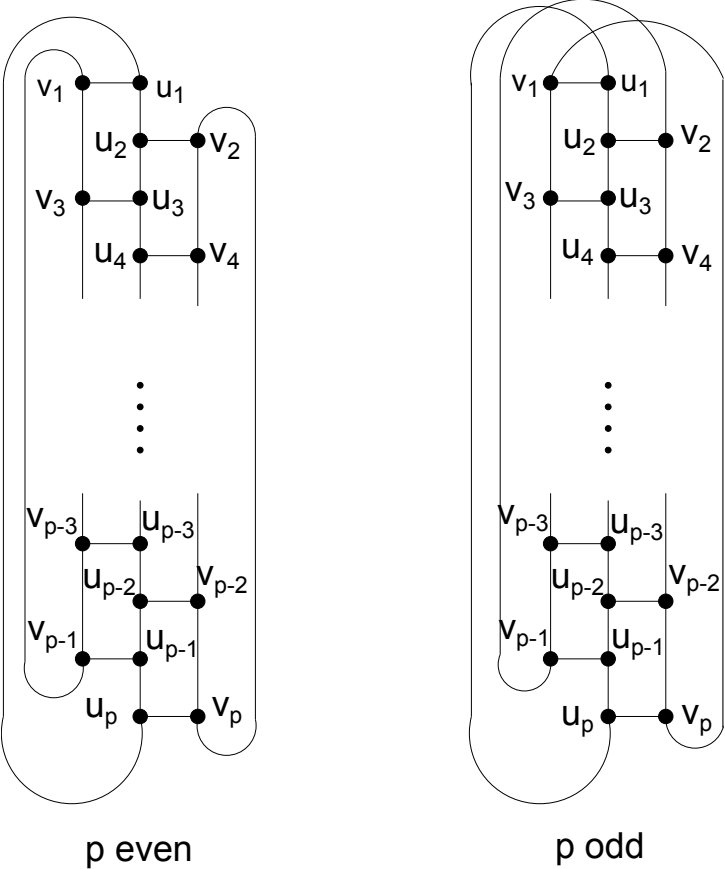

Figure 1: Biladders

The following is our first main result.

(1.3) *Let G, H be non-isomorphic cyclically 5-connected cubic graphs such that not both of them are biladders, let H contain G topologically, and assume that if G is isomorphic to the Petersen graph, then H does not topologically contain the biladder on 14 vertices (that is, for $p = 7$), and if G is isomorphic to the Dodecahedron, then H does not topologically contain the biladder on 24 vertices (that is, for $p = 12$). Then there exists a cyclically 5-connected handle or circuit expansion G' of G such that H contains G' topologically.*

There is a variation of (1.3), which is easier to apply, but which involves a stronger assumption about the graph H . Dodecahedral connectivity is defined in Section 5.

(1.4) *Let G, H be non-isomorphic cyclically 5-connected cubic graphs such that not both of them are biladders, let H be dodecahedrally connected, let H contain G topologically, and assume that if G is isomorphic to the Petersen graph, then H does not topologically contain the biladder on 14 vertices (that is, for $p = 7$), and if G is isomorphic to the Dodecahedron, then H does not topologically contain the biladder on 24 vertices (that is, for $p = 12$). Then there exists a cyclically 5-connected handle expansion G' of G such that H topologically contains G' .*

Since every biladder is either planar (if p is even), or topologically contains the Petersen graph (if p is odd) we deduce the following corollary.

(1.5) *Let G, H be non-isomorphic cyclically 5-connected cubic graphs, let G be non-planar, let H be dodecahedrally connected, let H contain G topologically, and assume that H does not topologically contain the Petersen graph. Then there exists a cyclically 5-connected handle expansion G' of G such that H topologically contains G' .*

The last three theorems describe how to obtain a bigger cyclically 5-connected cubic graph from a smaller one. But what are the initial graphs to start from? The graphs Petersen, Triplex, Box, Ruby and Dodecahedron are defined in Figure 2. The following theorem of McCuaig [6, 7] was also obtained in [1].

(1.6) *Every cyclically 5-connected cubic graph topologically contains one of Petersen, Triplex, Box, Ruby or Dodecahedron.*

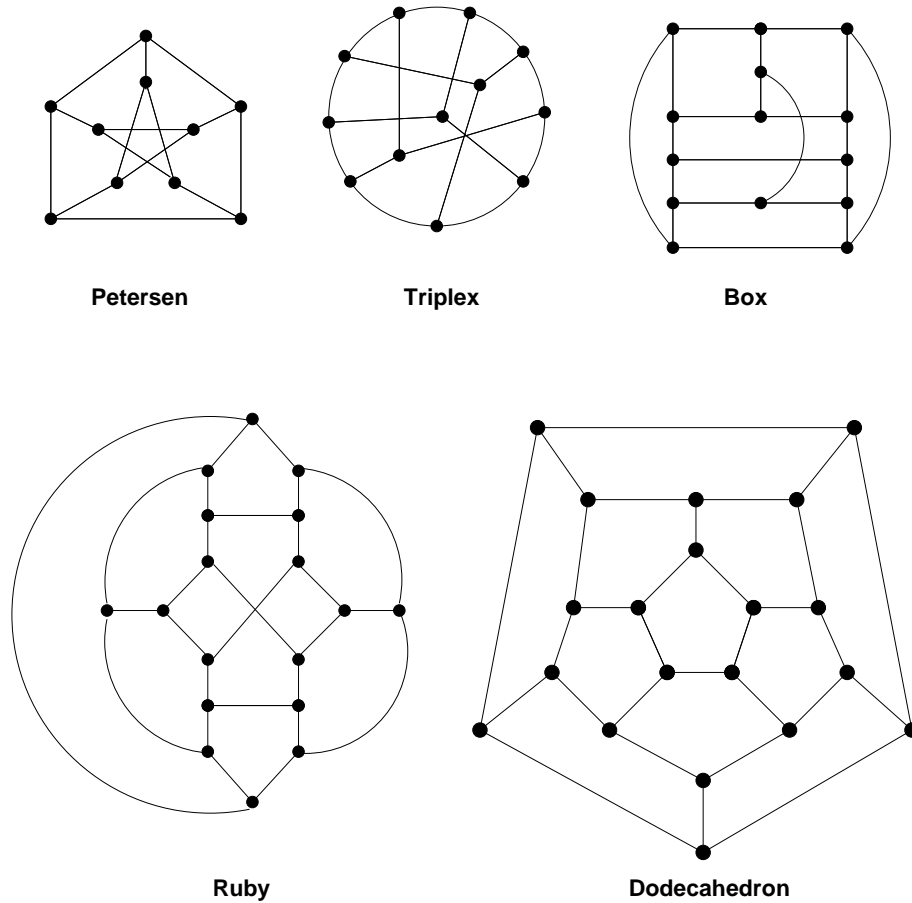

Figure 2. The five minimal cyclically 5-connected graphs

Theorems (1.3), (1.4) and (1.6) have the following corollary, the first part of which was proved for planar graphs in [2, 3], and for general graphs in [6, 7].

(1.7) *Every cyclically 5-connected cubic graph can be obtained from Triplex, Box, Ruby or a biladder by repeatedly applying the operations of handle expansion or circuit expansion. Every dodecahedrally connected cubic graph can be obtained from Triplex, Box, Ruby or a biladder by repeatedly applying the operation of handle expansion.*

It follows from (5.1) that a handle expansion of a dodecahedrally connected graph is again dodecahedrally connected.

Our proofs of (1.3) and (1.4) are indirect, and proceed by way of auxiliary results, stated as (4.10) and (5.6) below, that are themselves quite useful. Those auxiliary results allow G to violate the definition of cyclic 5-connectivity, but only in a limited way. For

instance, if G satisfies the definition of cyclic 5-connectivity, except for one circuit of length four, then we can still insist that G' be cyclically 5-connected. However, the operations that describe how to obtain G' are more complicated, and therefore we defer the exact statements to Section 4.

Let us introduce some terminology now. All graphs in this paper are finite and simple. Thus we may denote the edge of a graph with ends u and v by uv without any ambiguity. If G is a graph we denote its vertex-set and edge-set by $V(G)$ and $E(G)$, respectively. Let G be a graph. If K, L are subgraphs of G we denote by $K \cup L$ the graph with vertex-set $V(K) \cup V(L)$, edge-set $E(K) \cup E(L)$ and the obvious incidences. If $A \subseteq V(G)$ we denote by $\delta_G A$ (or δA if the graph can be understood from the context) the set of edges of G with one end in A and the other end in $V(G) - A$. An *edge-cut* of G is a set of edges of the form δA , where $A \subseteq V(G)$ and $\emptyset \neq A \neq V(G)$. If X is a vertex, a set of vertices, an edge, or a set of edges, we denote by $G \setminus X$ the graph obtained from G by deleting X . If X is a set of vertices we denote by $G|X$ the graph $G \setminus (V(G) - X)$. *Paths* and *circuits* have no “repeated” vertices and no “repeated” edges. A *quadrangle* is a circuit of length four. A graph G is *cubic* if every vertex of G has degree three and it is *subcubic* if every vertex has degree at most three. Let $k \geq 4$ be an integer. We say that a cubic graph G is *cyclically k -connected* if G is 3-connected, has at least $2k$ vertices, and for every edge-cut δA of G of cardinality less than k , one of $G \setminus A$, $G|A$ has no circuits.

Let e be an edge of a graph G . A graph H is obtained from G by *subdividing* e if H is obtained by deleting e , adding a new vertex $v \notin V(G)$, and joining v to both ends of e by new edges. We say that v is the *new vertex* of H . We say that a graph H *topologically contains* a graph G if some graph obtained from G by repeatedly subdividing edges is isomorphic to a subgraph of H .

The paper is organized as follows. In Sections 2 and 3 we introduce some terminology and prove several lemmas. In Section 4 we solve the following problem: Suppose that a cyclically 5-connected cubic graph H contains a graph G topologically and is minimal with this property, where G is “almost” cyclically 5-connected (quad-connected, as defined in the next section). What can we say about H ? In Section 5 we strengthen the conclusion of the result of Section 4 under the assumption that H is dodecahedrally connected. In

Section 6 we prove a preliminary version of (1.3), where we allow adding two handles, rather than one. We prove (1.3) and (1.4) in Section 7.

2. EXTENSIONS

Let G be a cubic graph. We say that G is *quad-connected* if

- G is cyclically 4-connected,
- G has at least 10 vertices,
- if G has more than one quadrangle, then it has at least 12 vertices, and
- for every edge-cut δA of G of cardinality exactly four, one of $G|A$ and $G \setminus A$ is isomorphic to K_2 or to a quadrangle.

Thus a cubic graph is cyclically 5-connected if and only if it is quad-connected and has no quadrangle. It follows that in a quad-connected graph no two quadrangles share an edge.

Let u, v, x, y be vertices of a graph G such that u is adjacent to v , x is adjacent to y , and $\{u, v\} \neq \{x, y\}$. We define $G + (u, v, x, y)$ to be the graph obtained from G by subdividing the edges uv and xy , where the new vertices are k and l , respectively, and adding an edge joining k and l . The vertices k, l (in this order) will be called the *new vertices* of $G + (u, v, x, y)$. We remark that if u, v, x, y are pairwise distinct and G has no circuits of length at most three, then neither does $G + (u, v, x, y)$. If the vertices u, v, x, y are pairwise distinct, then we say that $G + (u, v, x, y)$ is a *1-extension* of G . If, in addition, neither u nor v is adjacent to x or y , then we say that $G + (u, v, x, y)$ is a *long 1-extension* of G ; otherwise we say that it is *short*. Thus if G is cyclically 5-connected, then long 1-extension and handle expansion mean the same thing.

Now let C be a quadrangle in G . We say that the 1-extension $G + (u, v, x, y)$ is *based at C* if uv is an edge of C and $x, y \notin V(C)$, and we will apply the qualifiers long and short as in the previous paragraph. Let G be quad-connected, let C be a quadrangle in G , let $G + (u, v, x, y)$ be a short 1-extension of G based at C , and let k, l be the new vertices. Then one of u, v is adjacent to one of x, y , and so we may assume that, say, u is adjacent to x . Then $\{u, x, k, l\}$ is the vertex-set of a quadrangle D in G' . The next lemma implies that D is the only quadrangle of G' containing the edge kl . We say that D is the *new quadrangle* of G' .

(2.1) *Let G be a quad-connected cubic graph, and let G' be a 1-extension of G such that if G has a quadrangle, then G' is a 1-extension of G based at some quadrangle of G . Then G' is quad-connected. In particular, G' has at most one quadrangle that is not a quadrangle of G .*

Proof. The second assertion follows from the first, for every quadrangle of G' that is not a quadrangle of G uses the edge joining the new vertices of G' and in a quad-connected graph every edge belongs to at most one quadrangle. To prove that G' is quad-connected it suffices to verify the last condition in the definition of quad-connectivity, because the other conditions are clear. The graph G' is clearly 3-connected. Let k, l be the new vertices of G' . Let $\delta_{G'}A$ be an edge-cut of G' of cardinality at most four such that both $G'|A$ and $G'\setminus A$ contain circuits. We must show that $|\delta_{G'}A| = 4$ and that $G'|A$ or $G'\setminus A$ is a quadrangle. We have $4 \leq |A| \leq |V(G')| - 4$. Let $B = A - \{k, l\}$. Then $\emptyset \neq B \neq V(G)$, and so $\delta_G B$ is an edge-cut of G of cardinality at most four. Thus one of $G|B$ and $G\setminus B$ is a forest or a quadrangle.

Suppose first that $G|B$ is a quadrangle. Since $4 = |\delta_G B| \leq |\delta_{G'}A| \leq 4$, we see that $\delta_G B = \delta_{G'}A$. The definition of 1-extension implies that $\{u, v\} \not\subseteq B$ and $\{x, y\} \not\subseteq B$. Thus $G|B = G'|A$, and so $G'|A$ is a quadrangle, as desired. This completes the case where $G|B$ is a quadrangle.

By symmetry between $G|B$ and $G\setminus B$ we may therefore assume that $G|B$ is a forest. Since $|\delta_G B| \leq 4$ we see that $|B| \leq 2$, and since $|A| \geq 4$ we have $|B| = 2$, say $B = \{a, b\}$. Thus $A = \{a, b, k, l\}$, $|\delta_{G'}A| = 4$, and $G'|A$ is a quadrangle, as required. \square

(2.2) *Let G be a quad-connected cubic graph with at most one quadrangle, and let G' be a long 1-extension such that if G has a quadrangle C , then G' is a 1-extension based at C . Then G' is cyclically 5-connected.*

Proof. The graph G' is quad-connected by (2.1). Since the extension is long, the graph G' has no quadrangle, and hence is cyclically 5-connected. \square

(2.3) *Let G be a quad-connected cubic graph, let the vertices u_1, u_2, u_3, u_4, u_5 (in order) form the vertex-set of a path of G , let $G' = G + (u_1, u_2, u_4, u_5)$, and assume that either G*

is cyclically 5-connected, or G has a quadrangle C with $u_1, u_2 \in V(C)$ and $u_4, u_5 \notin V(C)$. Then G' is a short extension of G if and only if u_1 and u_5 are adjacent.

Proof. If u_1 and u_5 are adjacent, then G' is clearly a short extension. Conversely, if G' is a short extension, then one of u_1, u_2 is adjacent to one of u_4, u_5 . Since G has no triangles we may assume for a contradiction that either u_1 is adjacent to u_4 , or u_2 is adjacent to u_5 . In either case G has a quadrangle $D \neq C$, and hence G is not cyclically 5-connected. Thus C exists, but the existence of C and D contradicts the quad-connectivity of G . \square

Let G be a cyclically 4-connected cubic graph, let u_1, u_2, \dots, u_6 be the vertices of a path in G in order, let $G_1 = G + (u_1, u_2, u_3, u_4)$, and let k_1, l_1 be the new vertices of G_1 . We define $G \&(u_1, u_2, u_3, u_4, u_5, u_6)$ to be the graph $G_2 = G_1 + (u_3, l_1, u_5, u_6)$. Let k_2, l_2 be the new vertices of G_2 . We say that k_1, l_1, k_2, l_2 are the new vertices of $G \&(u_1, u_2, u_3, u_4, u_5, u_6)$.

(2.4) *Let G be a cubic graph, and let u_1, u_2, \dots, u_6 be vertices of G forming the vertex-set of a path in the order listed. Let $G' = G \&(u_1, u_2, u_3, u_4, u_5, u_6)$. Assume that G is quad-connected with at most one quadrangle, and that if it has a quadrangle, then it has a quadrangle C with $u_1, u_2 \in V(C)$ and $u_4, u_5, u_6 \notin V(C)$. Then G' is cyclically 5-connected.*

Proof. By (2.1) $G_1 = G + (u_1, u_2, u_3, u_4)$ is quad-connected, and it has exactly one quadrangle. By another application of (2.1) the graph G' is cyclically 5-connected, because it has no quadrangle. \square

(2.5) *Let G be a cubic graph, let u_1, u_2, \dots, u_5 be the vertices of a circuit of G in order, and assume that G is either cyclically 5-connected, or quad-connected with a quadrangle C such that $u_3, u_4 \in V(C)$ and $u_1, u_2, u_5 \notin V(C)$. Let v_1 be the neighbor of u_1 other than u_2 and u_5 , and let $G' = G + (u_3, u_4, u_1, v_1)$. Then G' is a long 1-extension of G .*

Proof. The vertex u_3 is not adjacent to v_1 in G , for otherwise G has a quadrangle D with vertex-set $\{v_1, u_1, u_2, u_3\}$, which implies that C exists, but the existence of C and D contradicts the quad-connectivity of G . Hence G' is a long 1-extension by (2.3). \square

(2.6) *Let G be a quad-connected cubic graph, and let C be a quadrangle in G with*

vertices u_1, u_2, u_3, u_4 in order. Let v_1 be the neighbor of u_1 not on C , and let v_2 be defined analogously. Let $w_1 \neq u_1$ be a neighbor of v_1 , and let $z_1 \neq v_1$ be a neighbor of w_1 . Then $G + (u_2, u_3, v_1, w_1)$ is a long 1-extension of G , and if $z_1 \neq v_2$ then $G + (u_1, u_2, w_1, z_1)$ is a long 1-extension of G .

Proof. The vertices w_1 and u_3 are not adjacent, for otherwise the set $\{u_1, u_2, u_3, u_4, v_1, w_1\}$ contradicts the quad-connectivity of G . Thus the 1-extension $G + (u_3, u_4, v_1, w_1)$ is long by (2.3), and so is $G + (u_1, u_2, w_1, z_1)$ if $z_1 \neq v_2$. \square

3. HOMEOMORPHIC EMBEDDINGS

Let G, H be graphs. A mapping η with domain $V(G) \cup E(G)$ is called a *homeomorphic embedding* of G into H if for every two vertices v, v' and every two edges e, e' of G

- (i) $\eta(v)$ is a vertex of H , and if v, v' are distinct then $\eta(v), \eta(v')$ are distinct,
- (ii) if e has ends v, v' , then $\eta(e)$ is a path of H with ends $\eta(v), \eta(v')$, and otherwise disjoint from $\eta(V(G))$, and
- (iii) if e, e' are distinct, then $\eta(e)$ and $\eta(e')$ are edge-disjoint, and if they have a vertex in common, then this vertex is an end of both.

We shall denote the fact that η is a homeomorphic embedding of G into H by writing $\eta : G \hookrightarrow H$, and we shall write $G \hookrightarrow H$ to mean that there exists a homeomorphic embedding of G into H . If K is a subgraph of G we denote by $\eta(K)$ the subgraph of H consisting of all vertices $\eta(v)$, where $v \in V(K)$, and all vertices and edges that belong to $\eta(e)$ for some $e \in E(K)$. It is easy to see that H contains G topologically if and only if there is a homeomorphic embedding $G \hookrightarrow H$.

Let G_0 be a quad-connected graph, let C_0 be a quadrangle in G , and let $n \geq 1$ be an integer. We say that G_n is an *n-extension* of G_0 based at C_0 if there exists a sequence $G_1, C_1, G_2, C_2, \dots, G_n$ such that for $i = 1, 2, \dots, n$, the graph G_i is a 1-extension of G_{i-1} based at C_{i-1} , and if $i < n$ then this 1-extension is short and C_i is the new quadrangle in G_i . We say that G_n is a *short n-extension* of G_0 if G_n is a short 1-extension of G_{n-1} , and we say that it is a *long n-extension* otherwise. We say that the sequence G_1, G_2, \dots, G_n is

a *generating sequence of the n -extension G_n from G_0 based at C_0* . We say that a graph H is an *extension of G_0* if it is an n -extension for some integer $n \geq 1$.

Let G, H, K be graphs, and let $\eta : G \hookrightarrow H$ and $\zeta : H \hookrightarrow K$. For $v \in V(G)$ we put $\xi(v) = \zeta(\eta(v))$, and for $e \in E(G)$ we define $\xi(e)$ to be the union of $\zeta(f)$ over all edges $f \in E(\eta(e))$. Then $\xi : G \hookrightarrow K$, and we write $\xi = \eta \circ \zeta$.

If G_0, G_1, \dots, G_n are as in the paragraph before the previous one, then for each $i = 1, 2, \dots, n$ there is a natural homeomorphic embedding $G_{i-1} \hookrightarrow G_i$, and hence there is a natural homeomorphic embedding $\iota : G_0 \hookrightarrow G_n$, called the *canonical embedding determined by the generating sequence G_1, G_2, \dots, G_n* . When there is no danger of confusion we will drop the reference to the generating sequence and simply talk about a canonical embedding.

We will frequently need to construct new homeomorphic embeddings from old ones by means of “rerouting”. We now introduce these constructions formally. Let G, H be graphs, and let $\eta : G \hookrightarrow H$ be a homeomorphic embedding. Let $e \in E(G)$, and let P' be a path in H of length at least one with both ends on $\eta(e)$, and otherwise disjoint from $\eta(G)$. Let P be the subpath of $\eta(e)$ with ends the ends of P' . Let $\eta'(e)$ be the path obtained from $\eta(e)$ by replacing the interior of P by P' , and let $\eta'(x) = \eta(x)$ for all $x \in V(G) \cup E(G) - \{e\}$. Then $\eta' : G \hookrightarrow H$ is a homeomorphic embedding, and we say that η' was obtained from η by *rerouting $\eta(e)$ along P'* .

Let e, f, g be three distinct edges of G , all incident with a vertex v of degree three. Let x be an interior vertex of $\eta(e)$, let y be an interior vertex of $\eta(f)$, and let P' be a path in H with ends x and y , and otherwise disjoint from $\eta(G)$. Let $\eta'(v) = y$, let $\eta'(e)$ be obtained from $\eta(e)$ by deleting the part from x to $\eta(v)$ (including $\eta(v)$ but not x) and adding P' , let $\eta'(f)$ be obtained from $\eta(f)$ by deleting the part from y to $\eta(v)$ (including $\eta(v)$ but not y), and let $\eta'(g)$ be obtained from $\eta(g)$ by adding the subpath of $\eta(f)$ with ends y and $\eta(v)$. For $z \in V(G) \cup E(G) - \{v, e, f, g\}$ let $\eta'(z) = \eta(z)$. Then $\eta' : G \hookrightarrow H$, and we say that η' was obtained from η by *rerouting $\eta(e)$ along P'* .

Let e be an edge of G with ends u, v of degree three, let f_1, f_2 be the other two edges incident with u , and let g_1, g_2 be the other two edges incident with v . Let x be an interior vertex of $\eta(f_1)$, let y be an interior vertex of $\eta(g_1)$, and let P' be a path in H with ends x and

y , and otherwise disjoint from $\eta(G)$. Let $\eta'(u) = x$, let $\eta'(v) = y$, let $\eta'(e) = P'$, let $\eta'(f_1)$ be the path obtained from $\eta(f_1)$ by deleting the subpath between x and $\eta(u)$ (including $\eta(u)$ but not x), let $\eta'(g_1)$ be the path obtained from $\eta(g_1)$ by deleting the subpath between y and $\eta(v)$ (including $\eta(v)$ but not y), let $\eta'(f_2)$ be obtained from $\eta(f_2)$ by adding the subpath of $\eta(f_1)$ between x and $\eta(u)$, and let $\eta'(g_2)$ be obtained from $\eta(g_2)$ by adding the subpath of $\eta(g_1)$ with ends y and $\eta(v)$. For $z \in V(G) \cup E(G) - \{u, v, e, f_1, f_2, g_1, g_2\}$ let $\eta'(z) = \eta(z)$. Then $\eta' : G \hookrightarrow H$, and we say that η' was obtained from η by rerouting $\eta(e)$ along P' .

Our next objective is to analyze augmenting paths relative to homeomorphic embeddings. The next lemma follows by a standard application of network flow theory. A proof may be found in [4, Lemma 3.3.3].

(3.1) *Let $k \geq 0$ be an integer, let G, H be cubic graphs, let $\delta_G A = \{e_1, e_2, \dots, e_k\}$ be an edge-cut of G of cardinality k , and for $i = 1, 2, \dots, k$ let the ends of e_i be $u_i \in A$ and $v_i \in V(G) - A$. Let $\eta : G \hookrightarrow H$ be a homeomorphic embedding, and assume that there is no edge-cut $\delta_H B$ of H of cardinality k with $\eta(A) \subseteq B$ and $\eta(V(G) - A) \subseteq V(H) - B$. Then there exist an integer n and disjoint paths Q_1, Q_2, \dots, Q_n in H , where Q_i has distinct ends x_i and y_i such that*

- (i) $x_1 \in V(\eta(G|A)) - \{\eta(u_1), \eta(u_2), \dots, \eta(u_k)\}$ and $y_n \in V(\eta(G \setminus A)) - \{\eta(v_1), \eta(v_2), \dots, \eta(v_k)\}$,
- (ii) for all integers $i \in \{1, 2, \dots, n-1\}$, the vertices $x_{i+1}, y_i \in V(\eta(e_t))$ for some $t \in \{1, 2, \dots, k\}$, and $\eta(u_t), x_{i+1}, y_i, \eta(v_t)$ are pairwise distinct and occur on $\eta(e_t)$ in the order listed,
- (iii) if $x_i, y_j \in V(\eta(e_t))$ for some $t \in \{1, 2, \dots, k\}$ and $i, j \in \{1, 2, \dots, n\}$ with $i > j + 1$, then $\eta(u_t), y_j, x_i, \eta(v_t)$ occur on $\eta(e_t)$ in the order listed, and
- (iv) for $i = 1, 2, \dots, n$, if a vertex of Q_i belongs to $V(\eta(G))$, then it is an end of Q_i .

In the situation described in (3.1) we call the sequence of paths $\gamma = (Q_1, Q_2, \dots, Q_n)$ an *augmenting sequence with respect to G, H, A and η* . Let F be a subgraph of G . We say that γ is *reduced modulo F* if the following conditions are satisfied:

- (i) If $e \in E(G|A)$ and $t \in \{1, 2, \dots, k\}$ are such that $x_1 \in V(\eta(e))$ and $y_1 \in V(\eta(e_t))$,

then e and e_t have no common end, and no end of e is adjacent to an end of e_t in $G \setminus E(F)$.

(ii) If $t \in \{1, 2, \dots, k\}$ and $f \in E(G \setminus A)$ are such that $x_n \in V(\eta(e_t))$ and $y_n \in V(\eta(f))$, then e_t and f have no common end, and no end of e_t is adjacent to an end of f in $G \setminus E(F)$.

(iii) If $t, t' \in \{1, 2, \dots, k\}$ and $i \in \{2, 3, \dots, n-1\}$ are such that $x_i \in V(\eta(e_t))$ and $y_i \in V(\eta(e_{t'}))$, then $t \neq t'$, u_t is not adjacent to $u_{t'}$ in $G \setminus E(F)$, and v_t is not adjacent to $v_{t'}$ in $G \setminus E(F)$.

Let G, H be graphs, let $\eta : G \hookrightarrow H$, and let F be a graph of minimum degree at least two (which includes the possibility that F is empty). We say that the homeomorphic embedding η fixes F if F is a subgraph of both G and H , $\eta(v) = v$ for every vertex $v \in V(F)$ and for every edge $e \in E(F)$ the image $\eta(e)$ is the path with edge-set $\{e\}$. In many of our lemmas and theorems we will be able to find a homeomorphic embedding that fixes a specified graph F . This feature will not be needed in this or the follow-up paper [11], but is included because it may be useful in future applications. As far as this paper and [11] are concerned, the reader may take F to be the null graph.

The lemma we need is the following.

(3.2) *Let G, H be cubic graphs, let $\delta_G A$ be an edge-cut in G such that no two members of $\delta_G A$ have a common end, let F be a graph of minimum degree at least two, let $\eta : G \hookrightarrow H$ be a homeomorphic embedding that fixes F , and let γ be an augmenting sequence with respect to G, H, A and η of length n . Let us assume that γ is minimal in the sense that there is no homeomorphic embedding $\eta' : G \hookrightarrow H$ that fixes F and an augmenting sequence with respect to G, H, A and η' of length n' such that $n' < n$. Then γ is reduced modulo F .*

Proof. Let G, H, A, η and γ be as stated, let $\delta_G A = \{e_1, e_2, \dots, e_k\}$, and let $\gamma = (Q_1, Q_2, \dots, Q_n)$. To prove that γ satisfies (i) let t and e be as in (i), and suppose for a contradiction that either e and e_t have a common end, or that some end of e is adjacent to some end of e_t in $G \setminus E(F)$. Since G and H are cubic, x_1 is an interior vertex of $\eta(e)$ and y_1 is an interior vertex of $\eta(e_t)$. Let η' be obtained from η by rerouting $\eta(e)$ (if e and f have a common end) or $\eta(g)$ (where g is an edge of $G \setminus E(F)$ adjacent to both e and f) along Q_1 .

Then $Q_2, Q_3, Q_4, \dots, Q_n$ is an augmenting sequence with respect to G, H, A and η' , and hence γ is not minimal, a contradiction.

Condition (ii) follows similarly, and so it remains to prove (iii). To that end let t, t' and i be as in (iii). Suppose first that $t = t'$. Then $\eta(u_t), x_i, y_{i-1}, x_{i+1}, y_i, \eta(v_t)$ all belong to $\eta(e_t)$ and occur on $\eta(e_t)$ in the order listed. Let η' be obtained from η by rerouting $\eta(e_t)$ along Q_i , and let Q be the union of Q_{i-1}, Q_{i+1} and the subpath of $\eta(e_t)$ with ends y_{i-1} and x_{i+1} . Then $Q_1, Q_2, \dots, Q_{i-2}, Q, Q_{i+2}, \dots, Q_n$ is an augmenting sequence with respect to G, H, A and η' , and hence γ is not minimal, a contradiction.

Thus $t \neq t'$. Next we suppose for a contradiction that u_t is adjacent to $u_{t'}$ in $G \setminus E(F)$. Let η' be obtained from η by rerouting $\eta(u_t u_{t'})$ along Q_i ; then $Q_{i+1}, Q_{i+2}, \dots, Q_n$ is an augmenting sequence with respect to G, H, A and η' , and hence γ is not minimal, a contradiction. Similarly we deduce that v_t is not adjacent to $v_{t'}$. Thus γ is reduced, as required. \square

Let G, H be cubic graphs, let $\eta : G \hookrightarrow H$ be a homeomorphic embedding, let e_1, e_2 be two edges of G with ends u_1, v_1 and u_2, v_2 , respectively, where u_1, v_1, u_2, v_2 are pairwise distinct, and assume that there exists a path Q in H with ends $x_i \in V(\eta(e_i))$ ($i = 1, 2$) and otherwise disjoint from $\eta(G)$. Let $G' = G + (u_1, v_1, u_2, v_2)$, and let k_1, k_2 be the new vertices of G' ; then G' is a 1-extension of G . For $i = 1, 2$ let $\eta'(k_i) = x_i$, let $\eta'(k_1 k_2) = Q$, let $\eta'(u_i k_i)$ be the subpath of $\eta(u_i v_i)$ with ends $\eta(u_i), x_i$, let $\eta'(v_i k_i)$ be defined analogously, and let $\eta'(x) = \eta(x)$ for all $x \in V(G) \cup E(G) - \{e_1, e_2\}$. Then $\eta' : G' \hookrightarrow H$ is a homeomorphic embedding. We say that the pair G', η' was obtained from η by routing the new edge along Q .

(3.3) *Let G be a cubic graph, let H be a cyclically 5-connected cubic graph, let F be a graph of minimum degree at least two, let $\eta : G \hookrightarrow H$ fix F , let C be a quadrangle in G that is disjoint from F , and assume that G has a circuit disjoint from C . Then there exist a 1-extension G' of G based at C and a homeomorphic embedding $\eta' : G' \hookrightarrow H$ that fixes F .*

Proof. Since H is cyclically 5-connected and $G \setminus V(C)$ contains a circuit, by (3.1) there exists an augmenting sequence $\gamma = (Q_1, Q_2, \dots, Q_n)$ with respect to $G, H, V(C)$ and η .

By (3.2) we may assume that γ is reduced modulo F . Let G', η' be obtained from η by routing the new edge along Q_1 . Then G', η' satisfy the conclusion of (3.3). \square

(3.4) *Let G, H be non-isomorphic cubic graphs, let F be a graph of minimum degree at least two, let $\eta : G \hookrightarrow H$ fix F , and let G and H be cyclically 4-connected. Then there exist a 1-extension G' of G and a homeomorphic embedding $\eta' : G' \hookrightarrow H$ such that η' fixes F .*

Proof. Since G is not isomorphic to H , and H is cyclically 4-connected, there exists a path P in H with at least one edge, with both ends on $\eta(G)$, and otherwise disjoint from $\eta(G)$. Let $x_1 \in \eta(e_1)$ and $x_2 \in \eta(e_2)$ be the ends of P , where $e_1, e_2 \in E(G)$. Let u, u_1 be the ends of e_1 , and let v, u_2 be the ends of e_2 . If u, u_1, v, u_2 are pairwise distinct, then $G' = G + (u, u_1, v, u_2)$ and η' obtained from η by routing the new edge along P satisfy the conclusion of the lemma. We may therefore assume that say $u = v$. The case when $u_1 = u_2$ can be reduced to the case $u_1 \neq u_2$ by a similar, though easier argument, and is omitted. Thus we assume that $u = v$ and $u_1 \neq u_2$.

Let G_1 be obtained from G by subdividing e_1 and e_2 and joining the new vertices by an edge. Let v_1 and v_2 be the new vertices of G_1 numbered so that v_1 resulted by subdividing e_1 . Let $\eta_1 : G_1 \hookrightarrow H$ be obtained by routing the new edge along P , and let $A = \{u, v_1, v_2\}$. Since H is cyclically 4-connected, there exists, by (3.1), an augmenting sequence with respect to G_1, H, A and η_1 . By (3.2) we may assume, by replacing η_1 by a different homeomorphic embedding if necessary, that there exists a path Q_1 that is the first term of a reduced augmenting sequence modulo F with respect to G_1, H, A and η_1 . Let $x \in V(\eta_1(G_1|A))$ and $y \in V(\eta_1(G_1 \setminus A))$ be the ends of Q_1 ; let $f \in E(G \setminus A)$ be such that $y \in V(\eta_1(f))$. From the symmetry between e_1 and e_2 we may assume that x belongs to $\eta(e_1) \cup \eta_1(v_1v_2)$. Thus $P \cup Q_1$ has a subpath R with one end in $\eta(e_1)$, the other end y and otherwise disjoint from $\eta(G)$. If f is not incident with u_1 , then the graph and homeomorphic embedding obtained from G by routing the new edge along R are as desired. Thus we may assume that f is incident with u_1 . Let $\eta' : G \hookrightarrow H$ be obtained from G by rerouting $\eta(e_2)[u, v_2]$ along P ; then the graph and homeomorphic embedding obtained from η' by routing the new edge along Q_1 are as desired. \square

4. FIXING A QUADRANGLE

Let G be a quad-connected cubic graph, and let C be a quadrangle in G . In this section we study the following problem: If H is cyclically 5-connected and topologically contains G , is there a quad-connected cubic graph G' such that G' is obtained from G by one of a set of well-defined operations, G is topologically contained in G' , G' is topologically contained in H and has fewer quadrangles than G ? The following simple result gives a preliminary answer. Let us recall that extensions were defined at the beginning of Section 3.

(4.1) *Let G be a quad-connected cubic graph, let H be a cyclically 5-connected cubic graph, let F be a graph of minimum degree at least two, and let $\eta : G \hookrightarrow H$ fix F . Let C be a quadrangle in G that is disjoint from F . Then there exist an integer $n \geq 1$, a long n -extension G' of G based at C and a homeomorphic embedding $\eta' : G' \hookrightarrow H$ that fixes F .*

Proof. Let n be the maximum integer such that there exists an n -extension G' of G based at C and a homeomorphic embedding $\eta' : G' \hookrightarrow H$ that fixes F . This is well-defined, because $2k \leq |V(J)| - |V(G)|$ for every k -extension J of G . We claim that G' is long. To prove the claim suppose to the contrary that it is short, and let C' be the new quadrangle of G' . It follows that C' is disjoint from F . By (3.3) there exists a 1-extension G'' of G' based at C' and a homeomorphic embedding $\eta'' : G'' \hookrightarrow H$ that fixes F . Then G'' is an $(n + 1)$ -extension of G based at C , contrary to the choice of n . This proves our claim that G' is a long extension of G , and hence the pair G', η' satisfies the conclusion of the lemma. □

In the rest of this section we strengthen (4.1) in two ways: we give a bound on the minimum integer n that satisfies the conclusion of (4.1), and we give an explicit list of long extensions based at C such that one of them is guaranteed to satisfy (4.1). We now introduce these extensions.

Let G be a quad-connected cubic graph, let C be a quadrangle in G , let u_1, u_2, u_3, u_4 be the vertices of C in order, for $i = 1, 2, 3, 4$ let v_i be the unique neighbor of u_i not on C , and let $v'_i \neq u_i$ be a neighbor of v_i . It follows that $v'_i \notin \{v_1, v_2, v_3, v_4\}$. Let $G_1 = G + (u_1, u_2, x, y)$ be a 1-extension of G with $x, y \notin V(C)$.

Figure 3. Type A–E expansions

- If G_1 is a long extension of G , we say that G_1 is a *type A expansion* of G based at C . See Figures 3, 4 and 5. Otherwise we may assume that say $x = v_1$ and $y = v_1'$. Let C_1 be the new quadrangle of G_1 ; thus C_1 has vertex-set $\{v_1, u_1, k, l\}$, where k, l are the new vertices of G_1 .
- Let $G_2 = G_1 + (v_1, l, a, b)$ be a 1–extension of G_1 . If G_2 is a long extension of G we say that G_2 is a *type B expansion* of G based at C , and that the sequence G_1, G_2 is

a *standard generating sequence* of G_2 .

- Let G_3 be $G_1 + (k, l, v_2, v'_2)$ or $G_1 + (u_1, v_1, v_4, v'_4)$. If G_3 is a long extension of G we say that G_3 is a *type C expansion* of G based at C , and that the sequence G_1, G_3 is a *standard generating sequence* of G_3 .

(We apologize for the double use of the letter C and hope it causes no confusion.)

- Let G_4 be the graph $G_1 + (u_1, k, u_3, v_3)$; we say that G_4 is a *type D expansion* of G based at C , and that the sequence G_1, G_4 is a *standard generating sequence* of G_4 .
- Let G'_5 be the graph $G_1 + (u_1, k, u_3, u_4)$, let a, b be the new vertices of G'_5 , and let G_5 be the graph $G'_5 + (b, u_4, v_3, v'_3)$. The graph G_5 is called a *type E expansion* of G based at C .

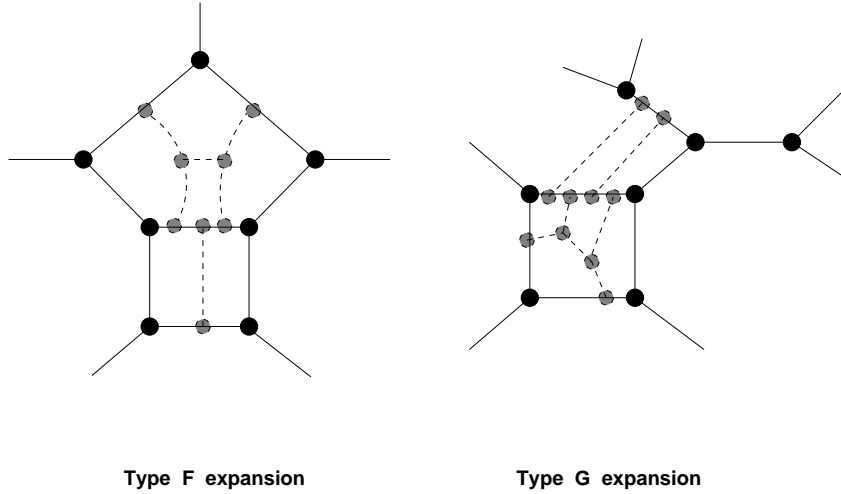

Figure 4. Type F and G expansions

- If $v'_1 = v'_2$, then let $G'_6 = G_1 + (u_2, k, v_2, v'_2)$, let k_2, l_2 be the new vertices of G'_6 , let $G''_6 = G'_6 + (k_2, k, u_3, u_4)$, and let $G_6 = G''_6 + (k, l, k_2, l_2)$. The graph G_6 is called a *type F expansion* of G based at C . We also say that G_6 is a *type F expansion* of G based on (u_1, u_2) , and that $k, l, k_2, l_2, k_3, l_3, k_4, l_4$ (in the order listed) are the *new vertices* of G_6 , where k_3, l_3 are the new vertices of G''_6 and k_4, l_4 are the new vertices

of G_6 . We say that

$$\{u_1, u_2, u_3, u_4, v_1, v_2, v'_1, k, l, k_2, l_2, k_3, l_3, k_4, l_4\}$$

is the *core* of the type F expansion G_6 .

- Let G_7 be a type F expansion of G_1 based on (u_1, k) . We say that G_7 is a *type G expansion of G* based at C .

(Again, apologies for the double use of the letter G.)

- Assume now that G has a quadrangle D with vertex-set $x_1, x_2, x_3, x_4 \in V(G) - V(C)$ such that x_1 is adjacent to u_1 , the vertices u_2 and x_2 have a common neighbor, and u_4 and x_4 have a common neighbor. Assume further that $\{x, y\} = \{x_1, x_2\}$, and let us recall that k, l are the new vertices of G_1 . Let G_8 be a type F expansion of G_1 based on (x_1, l) ; in those circumstances we say that G_8 is a *type H expansion of G* . The quad-connectivity of G implies that in this case $|V(G)| \leq 14$.

Figure 5. Type H expansion

It follows from the quad-connectivity of G that G_4, G_5, G_6, G_7, G_8 are long extensions of G . We offer the following easy but important remark. Let us recall that generating sequences were defined at the beginning of Section 3.

(4.2) Let G_0 be a quad-connected cubic graph, let C_0 be a quadrangle in G_0 , let G' be a type B, C, D, E, F, G or H expansion of G_0 based at C_0 , let G_1, G_2, \dots, G_k be a generating sequence of G' from G_0 based at C_0 , and let F be a graph of minimum degree at least two disjoint from C_0 . Let the vertices of C_0 be u_1, u_2, u_3, u_4 in order, let v_1 be the neighbor of u_1 not on C_0 , and let v'_1, v''_1 be the two neighbors of v_1 other than u_1 . If $G_1 = G_0 + (u_1, u_2, v_1, v'_1)$, then there exists a generating sequence G'_1, G'_2, \dots, G'_k of G' from G_0 based at C_0 such that

- for $i = 1, 2, \dots, k$ the graph G'_i is isomorphic to G_i ,
- $G'_1 = G_0 + (u_1, u_4, v_1, v''_1)$,
- if F is a subgraph of both G_0 and G_k , then F is a subgraph of G'_k , and
- if the sequence G_1, G_2 is a standard generating sequence of G_2 , then the sequence G'_1, G'_2 is a standard generating sequence of G'_2 .

The proof is clear.

(4.3) Let F be a graph of minimum degree at least two, let G be a quad-connected cubic graph, let C be a quadrangle in G , and let G_2 be a long 2-extension of G based at C such that F is a subgraph of both G and G_2 and F is disjoint from C . Then there exist an expansion G' of G of type A, B, C, or D based at C , and a homeomorphic embedding $\eta' : G' \hookrightarrow G_2$ such that η' fixes F .

Proof. Let G, C, G_2 be as stated, let u_1, u_2, u_3, u_4 be the vertices of C (in order), and let v_i be the neighbor of u_i not on C . Let $G_2 = G_1 + (u, v, x, y)$ and $G_1 = G + (u_1, u_4, v_1, v'_1)$, where $v'_1 \notin V(C)$ is adjacent to v_1 , and $\{u, v\}$ is one of $\{v_1, l_1\}, \{k_1, l_1\}, \{u_1, v_1\}, \{u_1, k_1\}$, where k_1, l_1 are the new vertices of G_1 . Let k_2, l_2 be the new vertices of G_2 .

First, if $\{u, v\} = \{v_1, l_1\}$, then G_2 is a type B expansion of G , and hence G_2 and the identity homeomorphic embedding $G_2 \hookrightarrow G_2$ satisfy the conclusion of the lemma. Second, let us assume that $\{u, v\} = \{k_1, l_1\}$. By considering the path $k_1 k_2 l_2$ we see that there exists a homeomorphic embedding $G + (u_1, u_4, x, y) \hookrightarrow G_2$ that fixes F , and hence we may assume that the 1-extension $G + (u_1, u_4, x, y)$ is short. It follows that $\{x, y\}$ equals one of $\{v_4, v'_4\}, \{u_3, v_3\}, \{u_2, u_3\}$ or $\{u_2, v_2\}$, where $v'_4 \neq u_4$ is a neighbor of v_4 . We break the analysis into three subcases. First, if $\{x, y\} = \{v_4, v'_4\}$, then G_2 is a type C expansion of G ,

and hence G_2 and the identity homeomorphic embedding $G_2 \hookrightarrow G_2$ satisfy the conclusion of the lemma. For the second subcase assume that $\{x, y\} = \{u_3, v_3\}$ or $\{u_2, u_3\}$. Let $G' = G + (u_3, u_4, v_1, v'_1)$; then G' is a long 1-extension of G by (2.6), and hence is a type A expansion of G . Let $\eta : G \hookrightarrow G_2$ be the canonical homeomorphic embedding determined by the generating sequence G_1, G_2 . Let $\eta' : G' \hookrightarrow G_2$ be obtained from η first by rerouting u_3u_4 along $k_1k_2l_2$, and then routing the new edge along k_2l_1 . Since $u_1, u_2, u_3, u_4, k_1, l_1, k_2, l_2 \notin F$ we deduce that η' fixes F . (In the future we will omit this kind of argument, because it will be clear that all the homeomorphic embeddings that we will construct will fix F .) The pair G', η' satisfies the conclusion of the lemma. The third and last subcase is that $\{x, y\} = \{u_2, v_2\}$. Let $G' = G + (u_2, u_3, v_1, v''_1)$, where $v''_1 \notin \{v'_1, u_1\}$ is the third neighbor of v_1 . Then G' is a long 1-extension of G by (2.6). Let $\eta' : G' \hookrightarrow G_2$ be obtained from η first by rerouting $\eta(u_1v_1)$ along $k_1k_2l_1$, then rerouting $\eta(k_1u_1u_2)$ along k_2l_2 , and finally routing the new edge along $\eta(u_2u_1v_1)$. Then G', η' satisfy the conclusion of the lemma. This completes the case $\{u, v\} = \{k_1, l_1\}$.

The third case $\{u, v\} = \{u_1, v_1\}$ is symmetric to the previous case by (4.2), and so we proceed to the fourth and last case, namely $\{u, v\} = \{u_1, k_1\}$. Let $G' = G + (u_1, u_4, x, y)$ and $\eta' : G' \hookrightarrow G_2$ be obtained from G, η by routing the new edge along $\eta(k_2l_2)$. We may assume that G' is a short 1-extension of G , for otherwise the lemma holds. Thus either $\{x, y\} = \{u_3, v_3\}$, or $\{x, y\} = \{v_4, v'_4\}$, where $v'_4 \neq u_4$ is a neighbor of v_4 . In the former case G_2 is a type D expansion of G , and so the lemma holds, and hence we may assume that the latter case holds. Since by (4.2) there is symmetry between u_1v_1 and k_1l_1 we deduce that also $\{x, y\} = \{v_2, v'_2\}$, where $v'_2 \neq u_2$ is a neighbor of v_2 . It follows that v_2 and v_4 are adjacent in G , contrary to the quad-connectivity of G . This completes the fourth case, and hence the proof of the lemma. \square

(4.4) *Let F be a graph of minimum degree at least two, let G be a quad-connected cubic graph, let C be a quadrangle in G , and let G_3 be a long 3-extension of G based at C such that F is a subgraph of both G and G_3 and F is disjoint from C . Then there exist a graph G' and a homeomorphic embedding $\eta' : G' \hookrightarrow G_3$ such that η' fixes F and G' is either a type E expansion or a long 1- or 2-extension of G based at C .*

Proof. Let G_1 be a short 1-extension of G based at C such that G_3 is a long 2-extension of G_1 based at the new quadrangle C_1 of G_1 . By (4.3) applied to the graph G_1 and circuit C_1 there exist an expansion G'_3 of G_1 of type A, B, C, or D based at C_1 , and a homeomorphic embedding $\eta'_3 : G'_3 \hookrightarrow G_3$ that fixes F . If G'_3 is of type A, then it is a long 2-extension of G based at C , and the lemma holds. Thus we may assume that G'_3 is of type B, C, or D. It follows that G_3 and G'_3 have the same number of vertices, and hence η'_3 is an isomorphism of G_3 and G'_3 . It follows that if the conclusion of the lemma holds for G'_3 , then it holds for G_3 . Therefore we may assume that $G'_3 = G_3$ and that η'_3 is the identity homeomorphic embedding. In other words, G_3 is a type B, C, or D expansion of G_1 based at C_1 .

Let G_2, G_3 be a standard generating sequence of the expansion G_3 . Then G_1, G_2, G_3 are quad-connected by (2.1). Let the vertices of C be u_1, u_2, u_3, u_4 in order. For $i = 1, 2, 3, 4$ let v_i be the neighbor of u_i not on C , let v'_i, v''_i be the neighbors of v_i different from u_i , and let w_i, w'_i be the neighbors of v''_i different from v_i . Let $G_2 = G_1 + (a_1, a_2, a_3, a_4)$. We may assume that $G_1 = G + (u_1, u_4, v_1, v'_1)$. Let u_5, v_5 be the new vertices of G_1 ; then $V(C_1) = \{v_1, u_1, u_5, v_5\}$. We claim the following.

- (1) *We may assume that $\{a_1, a_2\} = \{u_1, v_1\}$, and that $\{a_3, a_4\}$ is equal to one of $\{u_2, u_3\}$, $\{u_2, v_2\}$ or $\{v''_1, w'_1\}$.*

To prove (1) we first note that by (4.2) there is symmetry between $\{u_5, v_5\}$ and $\{u_1, v_1\}$, and so we may assume that $\{a_1, a_2\} \neq \{u_5, v_5\}$. Secondly, assume that $\{a_1, a_2\} = \{v_1, v_5\}$. Since G_2 is not a long extension of G_1 , one of a_3, a_4 equals one of v'_1, v''_1 . Let us assume that $a_3 = v''_1$; the argument for v'_1 is symmetric. We may assume from the symmetry that $a_4 = w'_1$. It follows from (4.2) applied to the graph G_1 and cycle C_1 that we may replace G_2 by the graph $G_1 + (u_1, v_1, v''_1, w_1)$ and thus arrange for the first assertion of (1) to hold. The case $\{a_1, a_2\} = \{u_1, u_5\}$ follows similarly. This proves that we may assume that $\{a_1, a_2\} = \{u_1, v_1\}$. Since G_2 is a short extension of G_1 , we see that $\{a_3, a_4\}$ is equal to one of $\{u_2, u_3\}$, $\{u_2, v_2\}$, $\{v''_1, w'_1\}$ or $\{v''_1, w_1\}$. Since the last two cases are symmetric, we may assume that one of the first three occurs. This proves (1).

Let k_2, l_2 be the new vertices of G_2 , let $G_3 = G_2 + (a_5, a_6, x, y)$, and let k_3, l_3 be the new vertices of G_3 . Let $\eta : G \hookrightarrow G_3$ be the canonical homeomorphic embedding determined

by the generating sequence G_1, G_2, G_3 . Since F has minimum degree at least two and is a subgraph of both G and G_3 we deduce that

$$(2) \quad u_1, u_2, u_3, u_4, u_5, v_1, v_5, k_2, l_2, k_3, l_3 \notin F.$$

To make the forthcoming case analysis easier to follow let us make an outline. There will be three supercases depending on $\{a_3, a_4\}$. These will be divided into cases depending on the type of the expansion G_3 , and the cases will sometimes be further divided into subcases depending on G_3 . In each subcase we shall construct a pair G', η' that satisfies the conclusion of the theorem. We first dispose of the supercase $\{a_3, a_4\} = \{u_2, u_3\}$. Let $G' = G + (u_2, u_3, v_1, v_1'')$, and let $\eta' : G' \hookrightarrow G_3$ be obtained from η by rerouting u_1v_1 along u_5v_5 and then routing the new edge along the path $l_2k_2v_1$. By (2.6) and (2) the pair G', η' satisfies the conclusion of the lemma. This completes the first supercase.

For the second supercase we assume that $\{a_3, a_4\} = \{u_2, v_2\}$. This will be divided into cases. As a first case assume that G_3 is a type B expansion of G_1 . Then $\{a_5, a_6\} = \{l_2, u_2\}$. Assume as a first subcase that $\{x, y\}$ is not equal to any of $\{v_3, v_3'\}, \{v_3, v_3''\}, \{u_4, v_4\}$, or $\{u_4, u_5\}$. Let G', η' be obtained from η first by rerouting u_1u_2 along l_2k_2 and then by routing the new edge along k_3l_3 if $\{x, y\} \neq \{u_5, v_5\}$ and along $k_3l_3v_5$ otherwise. Then G' is a long 1-extension of G , and so the lemma holds. We may therefore assume that $\{x, y\}$ is equal to one of the sets specified above. As a second subcase assume that $\{x, y\} = \{v_3, v_3'\}$ or $\{x, y\} = \{v_3, v_3''\}$. Then G_3 is isomorphic to a type E expansion of G , and so the lemma holds. Thirdly, let us assume that $\{x, y\} = \{u_4, v_4\}$ or $\{x, y\} = \{u_4, u_5\}$. Let $G' = G_1 + (u_1, u_5, u_3, v_3)$; then G' is a long 2-extension of G . Thus G' and the homeomorphic embedding obtained from the canonical homeomorphic embedding $G_1 \hookrightarrow G_3$ (determined by the generating sequence G_2, G_3) first by rerouting u_1u_2 along l_2k_2 , then rerouting u_3u_4 along k_3l_3 , and finally routing the new edge along u_1u_2 satisfy the conclusion of the lemma. This completes the case when G_3 is a type B expansion.

For the second case assume that G_3 is a type C expansion of G_1 . There are two subcases. Assume first that $\{a_5, a_6\} = \{u_1, u_2\}$. Then $\{x, y\} = \{u_4, v_4\}$, because $\{x, y\} \neq \{u_3, u_4\}$, since G_3 is a long 1-extension. Let $G' = G + (u_3, u_4, v_1, v_1')$ and let $\eta' : G' \hookrightarrow G_3$ be obtained from η first by rerouting u_1u_4 along k_3l_3 , and then by routing the new edge along $u_4u_5v_5$. The graph G' is a long 1-extension of G by (2.6), and hence (4.4) holds.

The second subcase is that $\{a_5, a_6\} = \{k_2, l_2\}$. Then say $x = v_1''$ and y is a neighbor of v_1'' different from v_1 . Since G_3 is a long extension of G we deduce that $v_2 \neq y$. Let $G' = G + (u_1, u_2, v_1'', y)$ and let $\eta' : G' \hookrightarrow G_3$ be obtained from η first by rerouting u_1u_2 along l_2k_2 and then routing the new edge along k_3l_3 . Then G' is a long 1-extension of G by (2.6), and hence (4.4) holds. This completes the second case. For the third case we assume that G_3 is a type D expansion of G_1 . Then $\{a_5, a_6\} = \{u_1, k_2\}$ and $\{x, y\} = \{v_1', v_5\}$. Let $G' = G_1 + (u_4, v_4, v_1, v_5)$; then G' is a long 1-extension of G_1 by (2.6), and hence it is a long 2-extension of G . Let η' be obtained from the canonical homeomorphic embedding $G_1 \hookrightarrow G_3$ first by rerouting u_1u_2 along k_2l_2 , then rerouting u_5v_5 along k_3l_3 , then rerouting u_3u_4 along u_1u_2 , and finally routing the new edge along u_5v_5 . Again, the pair G', η' satisfies the conclusion of the lemma. This completes the third case and hence the second supercase.

The third and last supercase is that $\{a_3, a_4\} = \{v_1'', w_1'\}$. We claim that we may assume that $w_1' = v_2$. Indeed, suppose that $w_1' \neq v_2$, let $G' = G + (u_1, u_2, v_1'', w_1')$ and let η' be obtained from η by rerouting u_1v_1 along u_5v_5 and by routing the new edge along $u_1k_2l_2$. Then G', η' satisfy the conclusion of the lemma by (2.6). This proves that we may assume that $w_1' = v_2$. From the symmetry we may assume that $v_2' = v_1''$. We distinguish three cases depending on whether G_3 is of type B, C, or D.

For the first case assume that G_3 is of type B. Then $\{a_5, a_6\} = \{l_2, v_1''\}$. Let us first dispose of the case when one of x, y is equal to v_2'' ; say $x = v_2''$. Then $y \neq v_2$, because G_3 is a long extension of G . Let G' and $\eta' : G' \hookrightarrow G_3$ be obtained from η by first rerouting v_2v_2'' along k_3l_3 , then rerouting u_1u_2 along k_2l_2 , then routing the first new edge along u_5v_5 , then routing the second new edge along u_1u_2 , and finally routing the third new edge along v_2v_2'' . Then G' is a type E expansion of G , and thus G', η' satisfy the conclusion of the lemma. We may therefore assume that $x, y \neq v_2'$. Let us assume next that $\{x, y\}$ is not equal to any of the pairs $\{u_1, u_5\}, \{u_1, u_2\}, \{u_2, u_3\}$. Let ξ be obtained from η by first rerouting $\eta(u_1v_1)$ along u_5v_5 , and then rerouting $\eta(v_2v_2')$ along $l_2k_2v_1$. Let G'' and $\eta'' : G'' \hookrightarrow G_3$ be obtained from ξ by routing the first new edge along u_1k_2 , and then routing the second new edge along l_2v_2' . Then G'' is a long 2-extension of G , and hence the pair G'', η'' satisfies the conclusion of the lemma. We may therefore assume that $\{x, y\}$ is equal to one of the pairs

$\{u_1, u_5\}, \{u_1, u_2\}, \{u_2, u_3\}$. Let G''' and $\eta''' : G''' \hookrightarrow G_3$ be obtained from ξ by routing the new edge along $v'_2 k_3 l_3$. Then G''' is a long 1-extension of G , and hence the pair G''', η''' satisfies the conclusion of the lemma. This completes the first case.

For the second case assume that G_3 is of type C. Then $\{a_5, a_6\} = \{v_1, v'_1\}$ or $\{a_5, a_6\} = \{k_2, l_2\}$. Thus we distinguish two subcases. Assume as a first subcase that $\{a_5, a_6\} = \{v_1, v'_1\}$. It follows that one of x, y equals v'_1 , say $x = v'_1$. Then $y \neq v_5$; let $y' \notin \{v_5, y\}$ be the third neighbor of v'_1 . Let ζ' be obtained from η by rerouting $v_1 v'_1$ along $k_3 l_3$. Let $G' = G + (u_1, u_4, v'_1, y')$ and $\eta' : G' \hookrightarrow G_3$ be obtained from ζ' by routing the new edge along $u_5 v_5 v'_1$; if $v_4 \neq y'$ then G', η' satisfy the lemma by (2.6). Thus we may assume that $y' = v_4$. Let $G'' = G + (u_1, u_4, v'_1, v_4) + (u_2, u_3, v_2, v''_2)$ and let η'' be obtained from ζ' first by rerouting $u_1 u_5$ along $v_1 v_5 u_5$, then by rerouting $u_2 v_2$ along $k_2 l_2$, then routing the first new edge along $v_5 v'_1$, and then routing the second new edge along $u_2 v_2$. Let G', η' be obtained from η'' by routing the new edge along $\eta_3(u_1 u_5)$. Then G' is a type E expansion of G , and thus G', η' satisfy the conclusion of the lemma. This completes the first subcase. For the second subcase assume that $\{a_5, a_6\} = \{k_2, l_2\}$; then $\{x, y\} = \{u_2, u_3\}$, because $\{x, y\} \neq \{u_2, v_2\}$ by the fact that G_3 is a long 1-extension of G . Let $G' = G + (u_2, u_3, v_1, v'_1)$ and let η' be obtained from η by rerouting $u_1 v_1$ along $u_5 v_5$ and then routing the new edge along $l_3 k_3 k_2 v_1$. Then G', η' satisfy the conclusion of the lemma by (2.6). This completes the second subcase and hence the second case.

For the third case assume that G_3 is of type D. Then $\{a_5, a_6\} = \{v_1, k_2\}$ and $\{x, y\} = \{u_4, u_5\}$. Let $G' = G + (u_1, u_2, v_2, v'_2) + (a, u_2, v_1, v'_1)$ (where a, b are the new vertices of $G + (u_1, u_2, v_2, v'_2)$) and $\eta' : G' \hookrightarrow G_3$ be obtained from η by rerouting $\eta(u_1 u_4)$ along $k_3 l_3$, then routing the first new edge along $k_2 l_2$, and then routing the second new edge along $u_1 u_5 v_5$. Then G' is a long 2-extension of G by (2.6), and hence the pair G', η' satisfies the conclusion of the lemma. This completes the third case, and hence the third supercase, and thus the proof of the lemma. \square

(4.5) *Let F be a graph of minimum degree at least two, let G be a quad-connected cubic graph, let C be a quadrangle in G , and let G_4 be a long 4-extension of G based at C such that F is a subgraph of both G and G_4 and F is disjoint from C . Then there exist a graph G' and a homeomorphic embedding $\eta' : G' \hookrightarrow G_4$ such that η' fixes F and G' is*

either a type F expansion of G based at C or a long n -extension of G based at C for some $n \in \{1, 2, 3\}$.

Proof. Similarly as in the proof of (4.4) we may assume that there exists a short 1-extension $G_1 = G + (u_1, u_4, v_1, v'_1)$ of G based at C such that G_4 is a type E expansion of G_1 based at the new quadrangle C_1 of G_1 . Since G_1 is short one of u_1, u_4 is adjacent to one of v_1, v'_1 , and so we may assume that u_1 is adjacent to v_1 . Let the vertices of C be u_1, u_2, u_3, u_4 in order, and for $i = 1, 2, 3, 4$ let v_i be the neighbor of u_i not on C . Let u_5, v_5 be the new vertices of G_1 ; then $V(C_1) = \{v_1, u_1, u_5, v_5\}$. By (4.2) there is symmetry between u_1v_1 and u_5v_5 ; hence there are only two cases to consider, namely $G_3 = G_2 + (u_1, v_1, u_2, u_3)$ and $G_3 = G_2 + (u_1, v_1, u_2, v_2)$, where $G_2 = G_1 + (u_5, v_5, v'_1, w)$, $G_4 = G_3 + (k_2, v_5, u_1, k_3)$, w is a neighbor of v'_1 different from v_5 and k_i, l_i are the new vertices of G_i for $i = 2, 3, 4$. Let us first dispose of the former case. Let G', η' be obtained from η by first rerouting u_1v_1 along $u_5k_2k_4v_5$, and then routing the new edge along $l_3k_3v_1$. Then by (2.6) G', η' satisfy the conclusion of the lemma and so we may assume that the latter case holds. We claim that we may assume that $w = v_4$. Otherwise let $G' = G + (u_1, u_4, v'_1, w)$ and η' be obtained from η by routing the new edge along $u_5k_2l_2$; then G', η' again satisfy the conclusion of the lemma by (2.6). Thus we may assume that $w = v_4$. Now G_4 is isomorphic to a type F expansion of G , and so the conclusion of the lemma is satisfied. \square

(4.6) *Let F be a graph of minimum degree at least two, let G be a quad-connected cubic graph, let C be a quadrangle in G , and let G_5 be a long 5-extension of G based at C such that F is a subgraph of both G and G_5 and F is disjoint from C . Then there exist a graph G' and a homeomorphic embedding $\eta' : G' \hookrightarrow G_5$ such that η' fixes F and G' is either a type G or type H expansion of G based at C or a long n -extension of G based at C for some $n \in \{1, 2, 3, 4\}$.*

Proof. Similarly as in the previous two proofs we may assume that there exists a short 1-extension $G_1 = G + (u_1, u_4, v_1, v'_1)$ of G based at C such that G_5 is a type F expansion of G_1 based at the new quadrangle C_1 of G_1 . Since G_1 is a short extension, one of u_1, u_4 is adjacent to one of v_1, v'_1 , and so we may assume that u_1 is adjacent to v_1 . Let the vertices of C be u_1, u_2, u_3, u_4 in order, and for $i = 1, 2, 3, 4$ let v_i be the neighbor of u_i not on

C . Let $v_1'' \notin \{u_1, v_1'\}$ be the third neighbor of v_1 . Let u_5, v_5 be the new vertices of G_1 ; thus $V(C_1) = \{v_1, u_1, u_5, v_5\}$. Since by (4.2) there is symmetry between u_1v_1 and u_5v_5 there are only three cases to consider, namely whether G_5 is based on u_1u_5 , v_1v_5 or u_5v_5 . If G_5 is based on u_1u_5 then G_5 is a type G expansion of G , and so G_5 and the identity homeomorphic embedding satisfy the conclusion of the lemma.

Next we assume that G_5 is based on v_1v_5 . It follows that v_1' and v_1'' have a common neighbor, say w , and $\{v_1, v_1', w, v_1''\}$ is the vertex-set of a quadrangle in G . Let z be the neighbor of v_1' in G other than v_1 and w . By a rerouting argument similar to ones used in previous proofs it is easy to construct a homeomorphic embedding $G + (u_1, u_4, v_1', z) \hookrightarrow G_5$ that fixes F . By (2.6) the lemma holds, unless $z = v_4$. Thus we may assume that $z = v_4$, and similarly that v_2 and v_1'' have a common neighbor. We deduce that G_5 is a type H expansion of G , as desired.

We may therefore assume that G_5 is based on u_5v_5 . Then v_4 and v_1' are adjacent. Let G' be obtained from G_5 by deleting the edge u_2u_3 and suppressing the resulting degree two vertices. Then G' is isomorphic to a type F expansion of G , and it is easy to construct a homeomorphic embedding $\eta' : G' \hookrightarrow G_5$ that fixes F . Hence G', η' satisfy the conclusion of the lemma. \square

(4.7) *Let F be a graph of minimum degree at least two, let G be a quad-connected cubic graph, let C be a quadrangle in G , let $n \geq 1$ be an integer, and let G_3 be a long n -extension of G based at C such that F is a subgraph of both G and G_3 and F is disjoint from C . Then there exist a graph G' and a homeomorphic embedding $\eta' : G' \hookrightarrow G_3$ such that η' fixes F and G' is a long n' -extension of G based at C for some $n' \in \{1, 2, 3, 4, 5\}$.*

Proof. Similarly as in the previous three proofs we may assume that there exists a short 1-extension $G_1 = G + (u_1, u_4, v_1, v_1')$ of G based at C such that G_3 is a type G or H expansion of G_1 based at the new quadrangle C_1 of G_1 . Thus one of u_1, u_4 is adjacent to one of v_1, v_1' , and so we may assume that u_1 is adjacent to v_1 . Let the vertices of C be u_1, u_2, u_3, u_4 in order, and for $i = 1, 2, 3, 4$ let v_i be the neighbor of u_i not on C . Let $v_1'' \notin \{u_1, v_1'\}$ be the third neighbor of v_1 in G . Let u_5, v_5 be the new vertices of G_1 . Thus $V(C_1) = \{v_1, u_1, u_5, v_5\}$. Then G_1 is quad-connected by (2.1).

We first assume that G_3 is a type G expansion of G_1 . Let G_2 be a 1-extension of G_1 such that G_3 is a type F expansion of G_2 , and let k_2, l_2 be the new vertices of G_2 . From the symmetry it suffices to consider three subcases. We consider them separately in the next three paragraphs.

As a first subcase assume that $G_2 = G_1 + (u_1, v_1, u_2, u_3)$. Let G', η' be obtained from η by first rerouting $\eta(u_1v_1)$ along $\eta(u_5v_5)$, and then routing the new edge along $l_2k_2v_1$. Then G', η' satisfy the conclusion of the lemma.

In the second subcase $G_2 = G_1 + (u_1, v_1, u_2, v_2)$, and G_3 is based on (u_1, k_2) . Let G' be obtained from G_3 by deleting the edge u_3u_4 , and suppressing the resulting vertices of degree two. Then G' is isomorphic to a type G expansion of G , and it is easy to construct a homeomorphic embedding $\eta' : G' \hookrightarrow G_3$ that fixes F . Then the pair G', η' satisfies the conclusion of the lemma.

In the third and last subcase $G_2 = G_1 + (u_5, v_5, v'_1, z)$, where z is a neighbor of v'_1 different from v_5 , and G_3 is based on (v_5, k_2) . Let $G' = G + (u_1, u_4, v'_1, z)$; by considering the path $u_5k_2l_2$ it is easy to construct a homeomorphic embedding $\eta' : G' \hookrightarrow G_3$ that fixes F . If $z \neq v_4$ then by (2.6) the pair G', η' satisfies the conclusion of the lemma. We may therefore assume that $z = v_4$. Let G' be obtained from G_3 by deleting the edges u_4v_4 and u_2u_3 and suppressing the resulting degree two vertices. and let η' be the canonical homeomorphic embedding $G' \hookrightarrow G_3$. Then G' is isomorphic to a type F expansion of G , and it is easy to construct a homeomorphic embedding $\eta' : G' \hookrightarrow G_3$ that fixes F . Hence the pair G', η' satisfies the conclusion of the lemma.

We now assume that G_3 is a type H expansion of G_1 based at C_1 . By (4.2) there is symmetry between u_1 and u_5 . Let D be as in the definition of expansion of type H. Thus some vertex of D is adjacent in G_1 to some vertex of C . By symmetry it suffices to consider only two subcases. In the first subcase $v''_1 \in V(D)$ is adjacent to $v_1 \in V(C_1)$, and a neighbor of v''_1 in D is adjacent to v'_1 . But then the set $V(D) \cup \{v_1, v'_1\}$ contradicts the quad-connectivity of G . In the second subcase some vertex of D is adjacent to u_5 , and the set $V(D) \cup \{u_1, u_2\}$ contradicts the quad-connectivity of G . \square

(4.8) *Let F be a graph of minimum degree at least two, let G be a quad-connected cubic graph, let C be a quadrangle in G , let $n \geq 1$ be an integer, and let G_3 be a long n -extension*

of G based at C such that F is a subgraph of both G and G_3 and F is disjoint from C . Then there exist a graph G' and a homeomorphic embedding $\eta' : G' \hookrightarrow G_3$ such that η' fixes F and G' is a type A, B, C, D, E, F, G or H expansion of G based at C .

Proof. Let us choose an integer $n_2 \geq 1$, a graph G_2 and a homeomorphic embedding $\eta_2 : G_2 \hookrightarrow G_3$ such that G_2 is a long n_2 -extension of G based at C , the homeomorphic embedding η_2 fixes F , and, subject to that, n_2 is minimum. Such a choice is possible, because $n_2 = n$, $G_2 = G_3$ and the identity homeomorphic embedding satisfy the requirements (except minimality).

We claim that there do not exist an integer n_1 , graph G_1 and homeomorphic embedding $\eta_1 : G_1 \hookrightarrow G_2$ such that $1 \leq n_1 < n_2$, G_1 is a long n_1 -extension of G based at C and η_1 fixes F . Indeed, otherwise the graph G_1 and homeomorphic embedding $\eta_1 \circ \eta_2$ violate the choice of G_2, η_2 . This proves our claim that n_1, G_1, η_1 do not exist.

It follows from (4.3), (4.4), (4.5), (4.6), and (4.7) that there exist a graph G' and a homeomorphic embedding $\eta' : G' \hookrightarrow G_2$ such that η' fixes F and G' is a type A, B, C, D, E, F, G or H expansion of G based at C . Thus G' and the homeomorphic embedding $\eta' \circ \eta_2$ satisfy the conclusion of the lemma. \square

(4.9) *Let G, H be cubic graphs, let F be a graph of minimum degree at least two, let $\eta : G \hookrightarrow H$ fix F , let C be a quadrangle in G disjoint from F , let G be quad-connected, and let H be cyclically 5-connected. Then there exist an expansion G' of G based at C of type A, B, C, D, E, F, G, or H and a homeomorphic embedding $\eta' : G' \hookrightarrow H$ that fixes F .*

Proof. By (4.1) there exist an integer $n \geq 1$, a long n -extension G_2 of G based at C , and a homeomorphic embedding $\eta_2 : G_2 \hookrightarrow H$ that fixes F . By (4.8) there exist a type A, B, C, D, E, F, G, or H expansion G_1 of G based at C and a homeomorphic embedding $\eta_1 : G_1 \hookrightarrow G_2$ that fixes F . Thus G_1 and $\eta_1 \circ \eta_2$ are as desired. \square

When F is the null graph we obtain the following corollary.

(4.10) *Let G, H be cubic graphs, let $G \hookrightarrow H$, let C be a quadrangle in G , let G be quad-connected, and let H be cyclically 5-connected. Then there exist an expansion G' of G based at C of type A, B, C, D, E, F, G, or H and a homeomorphic embedding $G' \hookrightarrow H$.*

5. DODECAHEDRAL CONNECTION

In this section we introduce dodecahedral connectivity, a notion of connectivity that is stronger than cyclic 5-connectivity. The main result of this section, (5.6) below, says that if the graph H in (4.9) is dodecahedrally connected, then the last three outcomes of (4.9) can be eliminated.

A *guild* is a pair (G, π) , where G is a graph with every vertex of degree 1 or 3, and π is a cyclic ordering of the set of vertices of G of degree 1. (We consider $(1, 2, 3, 4, 5)$ and $(3, 2, 1, 5, 4)$ to be the same cyclic ordering.) This is closely related to the notion of a society, introduced in [9]. If (G, π) and (G', π') are guilds and $\eta : G \hookrightarrow G'$ is a homeomorphic embedding, we say that η is a *homeomorphic embedding of (G, π) into (G', π')* if η maps π onto π' . (That is, if $\pi = (v_1, v_2, \dots, v_n)$, then π' is the cyclic ordering $(\eta(v_1), \eta(v_2), \dots, \eta(v_n))$.) If that is the case we write $\eta : (G, \pi) \hookrightarrow (G', \pi')$. If δA is an edge-cut of a cubic graph G of cardinality k such that δA is a matching, and v_1, v_2, \dots, v_k are all the vertices of $V(G) - A$ incident with an edge of δA , then let H be the graph $G|(A \cup \{v_1, v_2, \dots, v_k\})$. We say that $(H, (v_1, v_2, \dots, v_k))$ is a *shore guild corresponding to A* . Thus if $k > 2$ there are $(k - 1)!/2$ shore guilds corresponding to A .

Let G be the Dodecahedron, and let C be a circuit of G of length five with vertices u_1, u_2, \dots, u_5 in order. For $i = 1, 2, \dots, 5$ let v_i be the neighbor of u_i not on C . Let G' be the graph obtained from G by deleting the edges of C ; then $D = (G', (u_1, u_2, u_3, u_4, u_5))$ is a guild, called the *Dodecahedron guild*. Let $G'' = G' + (u, v, x, y)$ be a 1-extension of G' . We say that $D' = (G'', (u_1, u_2, u_3, u_4, u_5))$ is a *non-planar expansion of the Dodecahedron guild* if $\{u, v\} \neq \{u_i, v_i\}$ for all $i = 1, 2, \dots, 5$, and neither u nor v is equal or adjacent to x or y .

Let G be a cyclically 5-connected cubic graph. We say that G is *dodecahedrally connected* if for every edge-cut δA of cardinality five and every shore guild S corresponding to A , if $\eta : D \hookrightarrow S$ is a homeomorphic embedding of the Dodecahedron guild into S , then there exist a non-planar expansion D' of D and a homeomorphic embedding $\eta' : D' \hookrightarrow S$.

The following proposition from [11] is not needed in this paper, but is stated for the reader's convenience as it sheds some light on the seemingly mysterious definition of dodecahedral connection. A guild (G, π) is *planar* if G can be drawn in a closed disc Δ

with the vertices of degree one drawn in the boundary of Δ in the order given by π .

(5.1) *A cyclically 5-connected cubic graph G is dodecahedrally connected if and only if for every edge-cut δA of cardinality 5 with $|A| \geq 7$ and $|V(G) - A| \geq 7$, no shore guild corresponding to A is planar.*

We need the following lemma.

(5.2) *Let G, G_1, H be cubic graphs, let G be quad-connected, let F be a graph of minimum degree at least two, let C be a quadrangle in G , let G_1 be a type F expansion of G with core R based at C such that R is disjoint from F , let H be dodecahedrally connected, and let $\eta_1 : G_1 \hookrightarrow H$ be a homeomorphic embedding that fixes F . Then there exist a 1-extension $G_2 = G_1 + (u, v, x, y)$ of G_1 and a homeomorphic embedding $G_2 \hookrightarrow H$ that fixes F and such that $u, v \in R$, and either G_2 is a long 1-extension of G_1 or $x, y \notin R$.*

Proof. Let G, G_1, H, C, R, η_1 be as stated. Then δR is an edge-cut of G_1 of cardinality five such that some shore guild corresponding to R is isomorphic to the Dodecahedron guild. Let $\delta R = \{e_1, e_2, \dots, e_5\}$. If there exists an edge-cut δA of H of cardinality five with $\eta_1(R) \subseteq A$ and $\eta_1(V(G_1) - R) \subseteq V(H) - A$ then the conclusion follows from the definition of dodecahedral connection. We may therefore assume that no such edge-cut exists. Thus by (3.1) there exists an augmenting sequence $\gamma = (Q_1, Q_2, \dots, Q_n)$ with respect to G_1, H, R and η_1 . By (3.2) we may assume (by replacing η_1 by a different embedding if necessary) that the conclusion of (3.2) holds. Let G_2, η_2 be obtained from η_1 by routing the new edge along Q_1 ; it follows that G_2 and η_2 satisfy the conclusion of the lemma. \square

The following result will allow us to eliminate type F expansions when the graph H is dodecahedrally connected.

(5.3) *Let G, G_4, H be cubic graphs, let C be a quadrangle in G , let F be a graph of minimum degree at least two, let G be quad-connected, let G_4 be a type F expansion of G based at C with core R , and let $G_5 = G_4 + (u, v, x, y)$ be a 1-extension of G_4 such that $u, v \in R$, and either G_5 is a long 1-extension of G_4 or $x, y \notin R$. Assume further that F is a subgraph of both G and G_5 . Then there exist an integer $n \in \{1, 2, 3\}$, a long n -extension G' of G based at C , and a homeomorphic embedding $\eta' : G' \hookrightarrow G_5$ that fixes F .*

Proof. Let u_1, u_2, u_3, u_4 be the vertices of C in order, for $i = 1, 2, 3, 4$ let v_i be the neighbor of u_i not on C , and let v'_i, v''_i be the neighbors of v_i other than u_i . Since G has a type F expansion we may assume that $v'_1 = v'_2$. Let $w \notin \{v_1, v_2\}$ be the third neighbor of v'_1 . Choose G_1, G_2, G_3 such that each of $G, G_1, G_2, G_3, G_4, G_5$ is a 1-extension of the previous. For $i = 0, 1, 2, 3, 4$ let η_i be the canonical homeomorphic embedding $G_i \hookrightarrow G_5$ determined by the generating sequence $G_{i+1}, G_{i+2}, \dots, G_5$, where G_0 means G , for $i = 1, 2, 3, 4$ let k_i, l_i be the new vertices of G_i , and let $G_1 = G + (u_1, u_2, v_1, v'_1)$, $G_2 = G_1 + (k_1, u_2, v_2, v'_1)$, $G_3 = G_2 + (k_1, k_2, u_3, u_4)$ and $G_4 = G_3 + (k_1, l_1, k_2, l_2)$. Then $R = \{u_1, u_2, u_3, u_4, v_1, v_2, v'_1, k_1, l_1, k_2, l_2, k_3, k_4, l_4\}$. From (2.6) we deduce that

- (1) *the vertices in $R \cup \{v''_1, w, v''_2, v_3, v_4\}$ are pairwise distinct, except that possibly $w = v_3$ or $w = v_4$, but not both.*

We also point out for future reference that

- (2) *there is symmetry fixing v'_1, w and taking $u_1, u_4, v_1, v''_1, v_4$ onto $u_2, u_3, v_2, v''_2, v_3$, respectively.*
- (3) *If $u \in \{k_1, k_2, k_3, k_4, l_4\}$ and $x, y \notin R - \{v'_1\}$ then the lemma holds.*

To prove (3) let u, x, y be as stated, and let $G' = G + (u_1, u_2, x, y)$ and η' be obtained from η_0 by routing the new edge along $\eta_5(k_5l_5) \cup Q$, where Q is an appropriate subpath of $\eta_4(G_4)$. Then G', η' satisfy the conclusion of the lemma, and (3) follows.

- (4) *If $u = l_3$, $\{x, y\} \cap \{v_3, v_4\} = \emptyset$, $\{x, y\} \neq \{u_1, k_1\}$ and $\{x, y\} \neq \{u_2, k_2\}$ then the lemma holds.*

To prove (4) we may assume by (2) that $\{x, y\}$ does not equal $\{u_2, v_2\}$, $\{k_1, k_4\}$ or $\{k_4, l_1\}$. Let G', η' be obtained from η_0 by rerouting $\eta_5(u_1v_1)$ along $\eta_1(k_1l_1)$, and then by routing the new edge along $Q \cup \eta_5(k_5l_5) \cup Q'$, where Q is $\eta_5(k_5l_3)$ if $v = k_3$ and null otherwise, and Q' is $\eta_5(l_5v_1)$ if $\{x, y\} = \{u_1, v_1\}$, a subpath of $\eta_4(k_2l_4) \cup \eta_4(l_4l_2) \cup \eta_4(l_4k_4)$ with ends $\eta_5(l_5)$ and $\eta_4(l_2)$ if $l_4 \in \{x, y\}$, and null otherwise. Then G', η' satisfy the conclusion of the lemma and (4) follows.

- (5) *If $\{u, v\} = \{k_3, l_3\}$, then the lemma holds.*

This follows immediately from (3) and (4).

(6) *If $u \in \{u_2, k_2\}$ and $x, y \notin \{k_1, v_2, l_2, u_3, l_3, k_4, l_4, v_2''\}$ then the lemma holds.*

To prove (6) let G' and η' be obtained from η_0 by first rerouting $\eta_0(u_2u_3)$ along $\eta_5(k_3l_3)$, then routing the first new edge along $\eta_5(k_1k_4) \cup \eta_5(k_4l_4) \cup \eta_5(l_4l_2)$, and then routing the second new edge along $\eta_5(k_5l_5) \cup Q$, where Q is $\eta_5(k_5u_2)$ if $v = u_3$, $\eta_5(k_5k_2)$ if $v = l_4$, and null otherwise. Then G', η' satisfy the conclusion of the lemma, because G' is a long 2-extension of G . This proves (6).

(7) *If v_3 and v_2'' are adjacent, then the lemma holds.*

To prove (7) let G', η' be obtained from η_0 by

- first rerouting $\eta_4(u_2u_3)$ along $\eta_4(k_3l_3)$,
- then rerouting $\eta_4(k_2u_2) \cup \eta_4(u_2v_2)$ along $\eta_2(k_2l_2)$,
- then rerouting $\eta_4(u_1v_1)$ along $\eta_1(k_1l_1)$,
- then rerouting $\eta_4(k_1k_3)$ along $\eta_4(k_4l_4)$,
- then rerouting $\eta_4(v_3v_2'')$ along $\eta_4(u_3u_2) \cup \eta_4(u_2v_2)$,
- then routing the first new edge along $\eta_4(u_2k_2)$,
- then routing the second new edge along $\eta_4(k_1k_3)$,
- and finally routing the third new edge along $\eta_4(u_1v_1)$.

Then G' is a type E expansion of G , and hence the pair G', η' satisfies the conclusion of the lemma. This proves (7).

(8) *If $\{u, v\}$ is one of $\{u_2, u_3\}$, $\{u_3, l_3\}$, $\{l_3, u_4\}$ or $\{u_1, u_4\}$, then the lemma holds.*

To prove (8) we may assume by (2) that $\{u, v\} = \{u_2, u_3\}$ or $\{u_3, l_3\}$. Assume first that $v_3, v_4 \notin \{x, y\}$. Let G', η' be obtained from η_0 by

- first rerouting $\eta_4(u_1u_4)$ along $\eta_4(l_3k_3)$,
- then rerouting $\eta_4(k_3k_1) \cup \eta_4(k_1u_1) \cup \eta_4(u_1v_1)$ along $\eta_4(k_2l_4) \cup \eta_4(l_4k_4) \cup \eta_4(k_4l_1)$,
- then rerouting $\eta_4(l_1v_1')$ along $\eta_4(l_4l_2)$ and
- finally routing the new edge along $\eta_5(k_5l_5) \cup Q$, where Q is either null, or a path of $\eta_4(G_4)$ with one end $\eta_5(l_5)$, the other end in $\eta'(v_1v_1'')$, and otherwise disjoint from $\eta'(G)$.

The graph G' is a long extension of G , unless $\{u, v\} = \{u_3, l_3\}$ and $\{x, y\} = \{k_2, l_4\}$, in which case (8) follows from (4). Thus (8) holds if $v_3, v_4 \notin \{x, y\}$, and so we may assume

that either $x = v_3$ or $x = v_4$. As a second case assume that $x = v_4$. If $\{u, v\} = \{u_2, u_3\}$, then (8) follows from (6), and so let $\{u, v\} = \{u_3, l_3\}$. Let G' be obtained from G_4 by deleting the edges k_2l_4 and k_4l_1 and suppressing degree two vertices. Then G' is isomorphic to a type E expansion of G , and so (8) follows. This completes the second case. Thirdly, let $x = v_3$. Since the cases $\{u, v\} = \{u_2, u_3\}$ and $\{u, v\} = \{u_3, l_3\}$ are symmetric by (4.2), we may assume that $\{u, v\} = \{u_2, u_3\}$. If v_3 and v_2'' are adjacent, then (8) follows from (7); otherwise it follows from (6). This proves (8).

(9) *If $u = k_3$ then the lemma holds.*

To prove (9) let $u = k_3$. By (5) we may assume that $v \neq l_3$ (and hence $\{x, y\} \neq \{k_4, l_4\}$), by (3) we may assume that $\{x, y\} \cap R \neq \emptyset$, and by (2) we may assume that $\{x, y\} \neq \{u_2, v_2\}$ and $\{x, y\} \neq \{l_1, k_4\}$. By (8) we may assume that $\{x, y\} \neq \{u_2, u_3\}$ and $\{x, y\} \neq \{u_1, u_4\}$. Let G', η' be obtained from η_0 first by rerouting $\eta_4(k_1k_3) \cup \eta_4(k_3k_2)$ along $\eta_4(k_1k_4) \cup \eta_4(k_4l_4) \cup \eta_4(l_4k_2)$, then rerouting $\eta_4(u_1v_1)$ along $\eta_4(k_4l_1)$, and finally routing the new edge along $\eta_4(l_3k_3) \cup \eta_5(k_3k_5) \cup \eta_5(k_5l_5) \cup Q$, where Q is either null or $\eta_5(l_2l_5)$ or $\eta_5(v_1l_5)$. If $\{x, y\} \neq \{u_4, v_4\}$ and $\{x, y\} \neq \{u_3, v_3\}$ then G' is a long extension of G , and hence the lemma holds. From the symmetry we may assume that $\{x, y\} = \{u_4, v_4\}$. If $\{u, v\} = \{k_3, k_2\}$ then (9) follows from (6), and so we may assume that $\{u, v\} = \{k_1, k_3\}$. Let G', η' be obtained from η_0 by first rerouting $\eta_4(u_1u_4)$ along $\eta_5(k_5l_5)$, then rerouting $\eta_4(k_1u_1) \cup \eta_4(u_1v_1)$ along $\eta_4(k_1k_4) \cup \eta_4(k_4l_1)$, and then routing the new edge along $\eta_4(u_4u_1) \cup \eta_4(u_1v_1)$. Then G', η' satisfy the conclusion of the lemma, and hence (9) holds.

(10) *If $u \in \{l_1, k_4\}$ and $x = v_2$ then the lemma holds.*

To prove (10) we first define two paths Q, Q' . Let Q be the path of $\eta_4(v_2l_2) \cup \eta_4(v_2u_2) \cup \eta_4(v_2v_2'')$ with one end $\eta_5(l_5)$ and the other end in $\eta_4(v_2u_2) \cup \eta_4(v_2v_2'')$, and let Q' be the path of $\eta_1(k_1l_1) \cup \eta_0(v_1v_1') \cup \eta_4(k_4l_4)$ with one end $\eta_5(k_5)$ and the other end in $\eta_0(v_1v_1')$. Let $G' = G + (u_1, u_2, v_1', w)$ and η' be obtained from η_0 by rerouting an appropriate path along $Q \cup \eta_5(l_5k_5) \cup Q'$, and then routing the new edge along $\eta_2(k_2l_2) \cup \eta_2(l_2v_1')$. Then G', η' satisfy the conclusion of the lemma, thus proving (10).

(11) *If $\{u, v\}$ equals one of $\{u_2, v_2\}$, $\{u_1, v_1\}$, $\{u_2, k_2\}$ or $\{u_1, k_1\}$, then the lemma holds.*

To prove (11) we may assume by (2) that $\{u, v\} = \{u_2, v_2\}$ or $\{u, v\} = \{u_2, k_2\}$. If $\{x, y\} = \{u_4, v_4\}$ or $\{x, y\} = \{v_3, v'_3\}$, where $v'_3 \neq u_3$ is a neighbor of v_3 , then (11) follows from (6) and (7). If $\{x, y\} = \{k_1, k_3\}$ then (11) follows from (9), and if $\{x, y\} = \{k_4, l_4\}$, then (11) follows from (10). We may therefore assume that none of the above hold. Let G', η' be obtained from η_0 by first rerouting $\eta_4(u_1u_4)$ along $\eta_4(k_3l_3)$, then rerouting $\eta_4(v_1l_1)$ along $\eta_1(k_1l_1)$, then rerouting $\eta_4(u_2v_2)$ along $\eta_2(k_2l_2)$, then rerouting $\eta_4(l_2v'_1)$ along $\eta_4(k_4l_4)$, and finally routing the new edge along $Q \cup \eta_5(k_5l_5) \cup Q'$, where Q is either null or $\eta_5(k_5u_2)$, and Q' is either null or a subpath of $\eta_4(l_2v'_1) \cup \eta_4(u_4u_1) \cup \eta_4(v_1l_1)$ with one end $\eta_5(l_5)$ and the other end in $\{\eta_4(v'_1), \eta_4(u_1), \eta_4(v_1)\}$. Then the graph G' is a long extension of G , and hence (11) holds.

(12) *If $u \in \{l_1, k_4\}$, $x \in V(G) - (R \cup \{v''_1, w\})$ and $y \neq v''_1$, then the lemma holds.*

To prove (12) let G', η' be obtained from η_0 first by rerouting $\eta_4(u_4u_1)$ along $\eta_4(k_3l_3)$, then rerouting $\eta_4(k_1k_3)$ along $\eta_4(k_2l_4) \cup \eta_4(l_4k_4) \cup \eta_4(k_4k_1)$, then by rerouting $\eta_0(v_1v'_1)$ along $\eta_4(l_4l_2)$, then routing a first new edge along $\eta_4(k_1k_3)$, and finally routing a second new edge along $Q \cup \eta_5(k_5l_5)$, where Q is a suitable path of $\eta_4(G_4)$ with one end $\eta_5(k_5)$ and the other end in $\eta_4(k_1k_4) \cup \eta_4(k_4l_4)$. Then G', η' satisfy the conclusion of (12) thus proving (12).

(13) *If $\{u, v\} = \{k_4, l_4\}$ then the lemma holds.*

This follows from (2), (3), (5), (8), (10), (11) and (12).

(14) *If $\{u, v\}$ equals one of $\{k_1, k_4\}$, $\{k_4, l_1\}$, $\{k_2, l_4\}$ or $\{l_4, l_2\}$ then the lemma holds.*

To prove (14) we may assume by (2) that $\{u, v\} = \{k_1, k_4\}$ or $\{u, v\} = \{k_4, l_1\}$. By (3), (5), (8), (10), (11) and (12) we may assume that $\{u, v\} = \{k_1, k_4\}$, and $\{x, y\} = \{l_2, v'_1\}$ or $\{x, y\} = \{v_1, v''_1\}$. Let $\{u, v\} = \{k_1, k_4\}$, and assume first that $\{x, y\} = \{l_2, v'_1\}$. Let G', η' be obtained from η_0 first by rerouting $\eta_0(v'_1l_2)$ along $\eta_4(l_1k_4) \cup \eta_4(k_4l_4) \cup \eta_4(l_4l_2)$, and then routing the new edge along $\eta_5(k_1k_5) \cup \eta_5(k_5l_5) \cup \eta_5(l_5v'_1)$. Then G', η' satisfy the conclusion of the lemma. We may therefore assume that $\{x, y\} = \{v_1, v''_1\}$. In this case let G', η' be obtained from η_0 by routing the first new edge along $\eta_4(k_1k_4) \cup \eta_4(k_4l_4) \cup \eta_4(l_4l_2)$, and routing the second new edge along $\eta_5(k_5l_5)$. Then G' is a long 2-extension of G by

(2.1) and (2.5) (or by (1)), and hence the pair G', η' satisfies the conclusion of the lemma. This proves (14).

(15) *If $\{u, v\} = \{v_2, l_2\}$ or $\{u, v\} = \{v_1, l_1\}$ then the lemma holds.*

To prove (15) we may assume by (2) that $\{u, v\} = \{v_1, l_1\}$. By (5), (8), (9), (10), (11) and (12) we may assume that $\{x, y\} = \{v_1'', z\}$, where $z \neq v_1$ is a neighbor of v_1'' . But then G_5 is isomorphic to $G_4 + (u_1, v_1, v_1'', z')$, where $z' \notin \{v_1, z\}$ is the third neighbor of v_1'' , and hence (15) follows from (11).

(16) *If $\{u, v\} = \{l_2, v_1'\}$ or $\{u, v\} = \{l_1, v_1'\}$ then the lemma holds.*

To prove (16) we may assume by (2) that $\{u, v\} = \{l_2, v_1'\}$. By (2), (5), (8), (9), (11), (12) and (14) we may assume that $\{x, y\} = \{v_2'', z\}$, where $z \neq v_2$ is a neighbor of v_2'' . Let G', η' be obtained from η_0 by first rerouting $\eta_4(v_2v_2'')$ along $\eta_5(k_5l_5)$, then rerouting $\eta_4(u_2v_2) \cup \eta_4(v_2l_2)$ along $\eta_2(k_2l_2)$, and finally routing the new edge along $\eta_4(u_2v_2) \cup \eta_4(v_2v_2'')$. If v_2'' is not adjacent to v_3 , then G' is a long extension of G by (2.1), and hence the pair G', η' satisfies the conclusion of the lemma. On the other hand if v_3 and v_2'' are adjacent, then (16) follows from (7). This completes the proof of (16).

The lemma now follows from (5), (8), (9), (11), (13), (14), (15) and (16). □

(5.4) *Let G, G_4, H be cubic graphs, let C be a quadrangle in G , let F be a graph of minimum degree at least two, let G be quad-connected, let G_4 be a type F expansion of G based at C such that its core is disjoint from F , let $\eta : G_4 \hookrightarrow H$ fix F , and let H be dodecahedrally connected. Then there exist an integer $n \in \{1, 2, 3\}$, a long n -extension G' of G based at C and a homeomorphic embedding $\eta' : G' \hookrightarrow H$ that fixes F .*

Proof. This follows immediately from (5.2) and (5.3). □

(5.5) *Let G, G_5, H be cubic graphs, let C be a quadrangle in G , let F be a graph of minimum degree at least two, let G be quad-connected, let G_5 be a type G or H expansion of G based at C , let F be a subgraph of both G and G_5 , and let H be dodecahedrally connected. Then there exist an integer $n \in \{1, 2, 3\}$, a long n -extension G' of G based at C and a homeomorphic embedding $\eta' : G' \hookrightarrow H$ that fixes F .*

Proof. Let G_1 be a short 1–extension of G such that G_5 is a type F expansion of G_1 based at the new quadrangle of G_1 . By (5.4) applied to G_1 and the new quadrangle of G_1 there exist an integer $k \in \{1, 2, 3\}$, a long k -extension G_2 of G_1 , and a homeomorphic embedding $G_2 \hookrightarrow H$. Then G_2 is a long $(k + 1)$ -extension of G based at C , and so if $k \leq 2$, then the lemma holds. We may therefore assume that $k = 3$. By (4.5) we may assume that there exist a type F expansion G_3 of G based at C and a homeomorphic embedding $G_3 \hookrightarrow H$ that fixes F . The conclusion of the lemma now follows from (5.4) applied to the graph G and quadrangle C . \square

(5.6) *Let G, H be cubic graphs, let C be a quadrangle in G , let F be a graph of minimum degree at least two disjoint from C , let $\eta : G \hookrightarrow H$ fix F , let G be quad-connected, and let H be dodecahedrally connected. Then there exist an expansion G' of G of type A, B, C, D, or E based at C , and a homeomorphic embedding $G' \hookrightarrow H$ that fixes F .*

Proof. By (4.9) there exist an expansion G_1 of G of type A, B, C, D, E, F, G or H and a homeomorphic embedding $\eta_1 : G_1 \hookrightarrow H$ that fixes F . We may assume that G_1 is of type F, G, or H, for otherwise G_1, η_1 satisfy the theorem. By (5.4) and (5.5) applied to G, G_1, H and η_1 there exist an integer $n \in \{1, 2, 3\}$, a long n -extension G_2 of G based at C and a homeomorphic embedding $\eta_2 : G_2 \hookrightarrow H$ that fixes F . By (4.3) and (4.4) there exist an expansion G_3 of G of type A, B, C, D, or E and a homeomorphic embedding $\eta_3 : G_3 \hookrightarrow H$ that fixes F , as desired. \square

6. A TWO-EXTENSION THEOREM

In this section we prove a preliminary weaker version of (1.3). In (6.1) we prove it when H is dodecahedrally connected, and in (6.2) we prove it for cyclically 5-connected graphs H .

(6.1) *Let G, H be cubic graphs, let G be cyclically 5-connected, let H be dodecahedrally connected, and let $\eta : G \hookrightarrow H$ be a homeomorphic embedding. Then there exist a cyclically 5-connected cubic graph G' and a homeomorphic embedding $\eta' : G' \hookrightarrow H$ such that G' is a 1- or 2-extension of G .*

Proof. Let G, H, η be as stated. By (3.4) there exist a 1–extension $G_0 = G + (u_2, v_3, u_1, v_4)$ of G and a homeomorphic embedding $\eta_0 : G_0 \hookrightarrow H$. Let u_3, u_4 be the new vertices of G_0 .

If G_0 is cyclically 5-connected, then G_0, η_0 satisfy the conclusion of (6.1), and so we may assume that G_0 is not cyclically 5-connected. By (2.1) we may assume that say u_1 is adjacent to u_2 . Then G_0 is quad-connected, and has a unique quadrangle C_0 , where $V(C_0) = \{u_1, u_2, u_3, u_4\}$. By (5.6) there exist an expansion G_2 of G_0 of type A, B, C, D or E based C_0 , and a homeomorphic embedding $\eta_2 : G_2 \hookrightarrow H$. If G_2 is of type A, then the pair G_2, η_2 satisfies the conclusion of the lemma, and so it remains to consider types B, C, D and E.

Let us assume now that G_2 is of type B, C or D, and let G_1, G_2 be a standard generating sequence for G_2 . Let $G_1 = G_0 + (a_1, a_2, v_1, w)$, where $a_1, a_2 \in V(C_0)$, $v_1, w \notin V(C_0)$, and let k_1, l_1 be the new vertices of G_1 . Since G_1 is a short extension of G_0 , by (2.1) we may assume that say a_1 is adjacent to v_1 , and hence G_1 has a unique quadrangle, say C_1 , and its vertex-set is $\{a_1, v_1, k_1, l_1\}$. Let $\xi : G \hookrightarrow G_2$ be the canonical homeomorphic embedding determined by the generating sequence G_0, G_1, G_2 , let $\zeta_0 = \xi \circ \eta_2$, let ζ_1 be obtained from ζ_0 by rerouting $\zeta_0(u_1 u_2)$ along $\eta_2(u_3 u_4)$, and let ζ_2 be obtained from ζ_0 by rerouting $\eta_2(a_1 v_1)$ along $\eta_2(k_1 l_1)$.

(1) *We may assume that $\{a_1, a_2\} = \{u_1, u_2\}$.*

To prove (1) we first notice that by (4.2) we may assume that $\{a_1, a_2\} = \{u_1, u_2\}$ or $\{a_1, a_2\} = \{u_3, u_4\}$. But if $\{a_1, a_2\} = \{u_3, u_4\}$, then by replacing η by ζ_1 we can arrange that (1) holds.

From the symmetry between u_1 and u_2 we may assume that $a_1 = u_1$ and $a_2 = u_2$. Then v_1 is the neighbor of u_1 in G_0 that does not belong to C_0 . Let v_2 be the neighbor of u_2 in G_0 that does not belong to C_0 .

(2) *We may assume that w and v_2 are adjacent in G .*

To prove (2) suppose that w and v_2 are not adjacent, and let $G' = G + (u_2, v_2, v_1, w)$ and η' be obtained from ζ_1 by routing the new edge along $\zeta_1(u_2 k_1) \cup \zeta_1(k_1 l_1)$. Since $G + (u_2, v_2, v_1, w)$ is cyclically 5-connected by (2.3), (2) holds.

By (2) G has a circuit with vertex-set $\{u_1, u_2, v_2, w, v_1\}$. Let v'_1 be the neighbor of v_1 not on this circuit, and let v'_2 be defined similarly. We distinguish cases depending on the type of the expansion G_2 .

Let us assume first that G_2 is a type B expansion of G_0 . Then $G_2 = G_1 + (v_1, l_1, x, y)$ for some $x, y \in V(G_1)$. Let k_2, l_2 be the new vertices of G_2 . Let us assume first that $\{x, y\} = \{u_4, v_4\}$. Let $G' = G + (u_2, v_2, v_1, v'_1)$ and η' be obtained from ζ_1 by first rerouting $\zeta_1(v_1u_1)$ along $\eta_2(k_2l_2)$, and then routing the new edge along $\eta_1(u_1u_2) \cup \eta_1(u_1v_1)$. Since $G + (u_2, v_2, v_1, v'_1)$ is cyclically 5-connected by (2.5), the pair G', η' satisfies the conclusion of the theorem, as required. We may therefore assume that $\{x, y\} \neq \{u_4, v_4\}$. Let G', η' be obtained from ζ_0 by routing the first new edge along $\eta_1(k_1l_1)$, and then routing the second new edge along $\eta_2(k_2l_2)$ (or along $\eta_2(k_2l_2) \cup \eta_2(l_2u_3)$ if $\{x, y\} = \{u_3, u_4\}$). Then G', η' satisfy the conclusion of the theorem. This completes the case when G_2 is a type B expansion of G_0 .

We now assume that G_2 is a type C expansion of G_0 . Since $G_1 + (k_1, l_1, v_2, w)$ is not cyclically 5-connected, there are only two cases to consider. Assume first that $G_2 = G_1 + (k_1, l_1, v_2, v'_2)$, and let k_2, l_2 be the new vertices of G_2 . Let $G' = G + (u_1, v_1, v_2, v'_2)$ and η' be obtained from ζ_2 by routing the new edge along $\eta_2(k_2l_2)$. Since G' is cyclically 5-connected by (2.5) the theorem holds. Secondly, let us assume that $G_2 = G_1 + (u_1, v_1, v_4, v'_4)$, where $v'_4 \neq u_4$ is a neighbor of v_4 in G , and let k_2, l_2 be the new vertices of G_2 . Let $G' = G + (v_1, v'_1, v_4, v'_4)$ and η' be obtained from ζ_2 by routing the new edge along $\eta_2(v_1k_2) \cup \eta_2(k_2l_2)$. If G' is cyclically 5-connected, then the pair G', η' is as desired. We may therefore assume that $G + (v_1, v'_1, v_4, v'_4)$ is not cyclically 5-connected, and hence v'_1 and v'_4 are adjacent by (2.3). Let G' and η' be obtained from ζ_2 by first rerouting $\zeta_2(v'_1v'_4)$ along $\eta_2(v_1k_2) \cup \eta_2(k_2l_2)$, then routing a first new edge along $\eta_1(u_3u_4)$ and then routing a second new edge along $\eta_2(k_2u_1)$. Then G' is isomorphic to $G_0 + (u_1, u_4, v'_1, v'_4)$. Since $G_0 + (u_1, u_4, v'_1, v'_4)$ is cyclically 5-connected by (2.3), the pair G', η' is as desired. This completes the case when G_2 is a type C expansion.

We now assume that G_2 is a type D expansion of G_0 ; then $G_2 = G_1 + (k_1, u_1, u_3, v_3)$. Let k_2, l_2 be the new vertices of G_2 . Let $G' = G + (v_1, w, u_2, v_3)$ and η' be obtained from ζ_1 by routing the new edge along $\eta_2(k_2l_2) \cup \eta_2(k_2k_1) \cup \eta_2(k_1l_1)$. Since G' is cyclically 5-connected by (2.5) the theorem holds in this case. This completes the case that G_2 is a type D expansion.

Finally we assume that G_2 is a type E expansion of G_0 . Let G_1, G'_2, G_2 be a stan-

standard generating sequence for G_2 . From the symmetry we may assume that $G'_2 = G_1 + (u_3, u_4, v_3, v'_3)$, where $v'_3 \neq u_3$ is a neighbor of v_3 , and $G_2 = G'_2 + (k'_2, u_3, k_1, u_1)$, where k'_2, l'_2 are the new vertices of G'_2 . Let k_2, l_2 be the new vertices of G_2 . Let G' and η' be obtained from ζ_0 by routing the first new edge along $\eta_2(l_2k_2) \cup \eta_2(k_2k'_2) \cup \eta_2(k'_2l'_2)$ and then routing the second new edge along $\eta_2(k_1l_1)$. Since G' is cyclically 5-connected by (2.4), the theorem holds in this case. This completes the case when G_2 is a type E expansion of G_0 , and hence the proof of the theorem. \square

Let us recall that circuit expansion was defined prior to (1.3).

(6.2) *Let G, H be non-isomorphic cyclically 5-connected cubic graphs, and let $\eta : G \hookrightarrow H$ be a homeomorphic embedding. Then there exist a cyclically 5-connected cubic graph G' and a homeomorphic embedding $\eta' : G' \hookrightarrow H$ such that G' is either a 1- or 2-extension or a circuit expansion of G .*

Proof. Let G, H, η be as stated. By (3.4) there exist a 1-extension $G_0 = G + (u_2, v_3, u_1, v_4)$ of G and a homeomorphic embedding $\eta_0 : G_0 \hookrightarrow H$. Let u_3, u_4 be the new vertices of G_0 . If G_0 is cyclically 5-connected, then G_0, η_0 satisfy the conclusion of (6.1), and so we may assume that G_0 is not cyclically 5-connected. By (2.1) we may assume that say u_1 is adjacent to u_2 . Then G_0 is quad-connected, and has a unique quadrangle C_0 , where $V(C_0) = \{u_1, u_2, u_3, u_4\}$. By (4.10) there exist an expansion G_2 of G_0 of type A, B, C, D, E, F, G or H based at C_0 , and a homeomorphic embedding $\eta_2 : G_2 \hookrightarrow H$. If G_2 is an expansion of type A, B, C, D or E then the theorem holds by the proof of (6.1). We may therefore assume that G_2 is an expansion of type F, G or H. Let ζ_1 be defined as in the proof of (6.1).

Assume first that G_2 is an expansion of type F. Since G is cyclically 5-connected, v_1 and v_4 have no common neighbor in G , and similarly v_2 and v_3 have no common neighbor in G . Therefore G_2 is based on either u_1u_2 , or u_3u_4 . In either case G_2 is a circuit expansion of G , and so the pair G_2, η_2 satisfies the conclusion of the theorem.

Secondly, let us assume that G_2 is an expansion of type G. Let G_1 be a short 1-extension of G_0 based at C_0 such that G_2 is a type F expansion of G_1 , and let C_1 be the unique quadrangle of G_1 . By replacing η by ζ_1 and by using symmetry we may assume that

$G_1 = G_0 + (u_1, u_2, v_1, w)$, where $w \neq u_1$ is a neighbor of v_1 . Let k_1, l_1 be the new vertices of G_1 ; then the vertex-set of C_1 is $\{u_1, v_1, l_1, k_1\}$. From claim (1) in the proof of (6.1) we may assume that w and v_2 are adjacent. Let G' be obtained from G_2 by deleting the edge v_2w and suppressing the resulting vertices of degree two, and let η' be the restriction of η_2 to G' . Then G' is isomorphic to a circuit expansion of G , and so the theorem holds.

Finally let us assume that G_2 is an expansion of type H. Using the same symmetry as before we may assume that G_0 has a quadrangle D with vertex-set $\{x_1, x_2, x_3, x_4\}$, where u_1 is adjacent to x_1 , the vertices u_2 and x_2 have a common neighbor, and u_4 and x_4 have a common neighbor, say z . Then the set $V(D) \cup \{u_1, z\}$ violates the dodecahedral connectivity of G . This completes the case when G_2 is a type H expansion, and hence a proof of the theorem. \square

7. A ONE-EXTENSION THEOREM

In this section we prove (1.3) and (1.4).

(7.1) *Let G, H be cyclically 5-connected cubic graphs, let u_1, u_2, u_3, u_4, u_5 (in order) be the vertices of a path of G , let $G_2 = G + (u_1, u_2, u_3, u_4) + (u_2, u_3, u_4, u_5)$, and let $\eta_2 : G_2 \hookrightarrow H$. Then there exist a cyclically 5-connected handle expansion G' of G and a homeomorphic embedding $G' \hookrightarrow H$.*

Proof. Let $v_2 \notin \{u_1, u_3\}$ be the third neighbor of u_2 , and let v_3 and v_4 be defined similarly. Let $G_1 = G + (u_1, u_2, u_3, u_4)$, let k_1, l_1 be the new vertices of G_1 , let k_2, l_2 be the new vertices of $G_1 + (u_2, u_3, u_4, u_5)$, and let η be the restriction of η_2 to G . Let ζ_1 be obtained from η by rerouting $\eta_2(u_2u_3)$ along $\eta_2(k_1l_1)$. By considering the path $\eta_2(l_2k_2) \cup \eta_2(k_2u_2)$ we can extend ζ_1 to a homeomorphic embedding $G + (v_2, u_2, u_4, u_5) \hookrightarrow H$. We deduce that if $G + (v_2, u_2, u_4, u_5)$ is cyclically 5-connected, then the lemma holds. Thus we may assume that that is not the case, and hence v_2 and u_5 are adjacent in G by (2.3).

Let $G' = G + (u_3, v_3, u_5, v_2)$ and η' be obtained from ζ_1 by first rerouting $\eta_2(v_2u_5)$ along $\eta_2(k_2l_2) \cup \eta_2(k_2u_2)$, and then by routing the new edge along $\eta_2(k_2u_3)$. Since G' is cyclically 5-connected by (2.5), the lemma follows. \square

(7.2) Let G be a cyclically 5-connected cubic graph, and let $\dots, u_{-1}, u_0, u_1, \dots$ and $\dots, v_{-1}, v_0, v_1, \dots$ be two doubly infinite sequences of (not necessarily distinct) vertices of G such that for all integers i , the neighbors of u_i are u_{i-1}, u_{i+1} and v_i , and the neighbors of v_i are v_{i-2}, v_{i+2} and u_i . Then there exists an integer $p \geq 5$ ($p \geq 10$ if p is even) such that $u_i = u_{i+p}$ and $v_i = v_{i+p}$ for all integers i , and the vertices $u_1, u_2, \dots, u_p, v_1, v_2, \dots, v_p$ are pairwise distinct. Thus G is a biladder.

Proof. Choose $p > 0$ minimum such that for some integer i , one of u_i, v_i equals one of u_{i+p}, v_{i+p} . Suppose first that $u_i = v_{i+p}$. Then $p > 2$, and the neighborhood set of u_i equals the neighborhood set of v_{i+p} , so one of u_{i-1}, u_{i+1}, v_i equals v_{i+p-2} , contrary to the choice of p . If $v_i = u_{i+p}$, then similarly one of $u_{i+p-1}, u_{i+p+1}, v_{i+p}$ equals v_{i+2} , again contrary to the choice of p .

So either $u_i = u_{i+p}$ or $v_i = v_{i+p}$; and then as before, it follows that $u_i = u_{i+p}$ and $v_i = v_{i+p}$ for all integers i . It follows from the choice of p that the vertices $u_1, u_2, \dots, u_p, v_1, v_2, \dots, v_p$ are pairwise distinct. \square

(7.3) Let G, H be cyclically 5-connected cubic graphs, let H be a long 2-extension of G , and assume that there does not exist a handle expansion G' of G which admits a homeomorphic embedding $G' \hookrightarrow H$. Then both G, H are biladders.

Proof. Since H is a 2-extension of G , there exist vertices v_1, v_3, u_3, u_2 of G and vertices a_1, a_2, a_3, a_4 of $G_1 = G + (v_1, v_3, u_3, u_2)$ such that $H = G_1 + (a_1, a_2, a_3, a_4)$. Let k_1, l_1 be the new vertices of G_1 . Then G_1 is not cyclically 5-connected, and so by (2.1) we may assume that v_3 is adjacent to u_3 in G . Thus G_1 is quad-connected and has a unique quadrangle C_1 , where C_1 has vertex-set v_3, u_3, l_1, k_1 . Furthermore, one of $\{a_1, a_2\}, \{a_3, a_4\}$ is equal to one of $\{v_3, u_3\}, \{u_3, l_1\}, \{l_1, k_1\}$ or $\{k_1, v_3\}$. From the symmetry (and making use of the homeomorphic embedding obtained from the canonical homeomorphic embedding $G \hookrightarrow H$ by rerouting $v_3 u_3$ along $k_1 l_1$) we may assume that either $\{a_1, a_2\} = \{v_3, u_3\}$, or $\{a_1, a_2\} = \{u_3, l_1\}$. Let $v_2 \neq u_3$ be a neighbor of u_2 in G . In the former case, since $G + (a_1, a_2, a_3, a_4)$ is not cyclically 5-connected, we may assume from the symmetry that $\{a_3, a_4\} = \{u_2, v_2\}$, in which case we obtain a contradiction from (7.1) applied to the path of G with vertex-set $\{v_1, v_3, u_3, u_2, v_2\}$.

We may therefore assume that $\{a_1, a_2\} = \{u_3, l_1\}$, and further (by replacing v_2 if necessary) that $\{a_3, a_4\} = \{v_2, v_4\}$, where $v_4 \neq u_2$ is a neighbor of v_2 . Then $v_1 \neq v_4$, because G is cyclically 5-connected. Thus G has a path P with vertex-set $v_1, v_3, u_3, u_2, v_2, v_4$ (in order) such that $H = G\&(v_1, v_3, u_3, u_2, v_2, v_4)$. (The $\&$ operator was defined prior to (2.4)). Let u_1 be the neighbor of u_2 not on P , and let u_4 be the neighbor of u_3 not on P . Assume that for some integers m, n with $m \leq 1$ and $n \geq 4$ we have already constructed (not necessarily distinct) vertices $u_m, u_{m+1}, \dots, u_n, v_m, v_{m+1}, \dots, v_n$ of G such that for all $i = m + 1, m + 2, \dots, n - 1$

- (i) u_i is adjacent in G to u_{i+1} and u_m is adjacent in G to u_{m+1} ,
- (ii) u_i is adjacent in G to v_i ,
- (iii) v_{i-1} is adjacent in G to v_{i+1} ,
- (iv) there exists a homeomorphic embedding

$$\eta_n : G\&(v_{n-3}, v_{n-1}, u_{n-1}, u_{n-2}, v_{n-2}, v_n) \hookrightarrow H,$$

and

- (v) there exists a homeomorphic embedding

$$\eta_m : G\&(v_m, v_{m+2}, u_{m+2}, u_{m+1}, v_{m+1}, v_{m+3}) \hookrightarrow H.$$

We shall construct $u_{m-1}, v_{m-1}, u_{n+1}, v_{n+1}, \eta_{m-1}, \eta_{n+1}$ such that (i)-(v) are satisfied for all $i = m, m + 1, \dots, n$.

Let $L = G\&(v_{n-3}, v_{n-1}, u_{n-1}, u_{n-2}, v_{n-2}, v_n)$, and let k, l, k', l' be the new vertices of L . Let η' be obtained from the restriction of η_n to G by rerouting $\eta_n(v_{n-1}u_{n-1})$ along $\eta_n(kl)$. By considering the path $\eta_n(k'l')$ we can extend η' to a homeomorphic embedding $\eta'' : G + (u_{n-1}, u_n, v_{n-2}, v_n) \hookrightarrow H$. Since $G + (u_{n-1}, u_n, v_{n-2}, v_n)$ is not cyclically 5-connected by hypothesis, we deduce from (2.3) that u_n, v_n are adjacent. Let $u_{n+1} \notin \{u_{n-1}, v_n\}$ be the third neighbor of u_n , and let $v_{n+1} \notin \{u_{n-1}, v_{n-3}\}$ be the third neighbor of v_{n-1} . By considering the homeomorphic embedding η'' and the path $\eta_n(u_{n-1}v_{n-1})$ we can construct a homeomorphic embedding $\eta_{n+1} : G\&(v_{n-2}, v_n, u_n, u_{n-1}, v_{n-1}, v_{n+1}) \hookrightarrow H$. The vertices u_{m-1}, v_{m-1} and homeomorphic embedding η_{m-1} are defined analogously.

This completes the definition of two doubly infinite sequences of vertices $\dots u_{-1}, u_0, u_1, \dots$ and $\dots v_{-1}, v_0, v_1, \dots$ of G such that (i), (ii), (iii) hold for all integers i . It follows from (7.2) that both G, H are biladders, as required. \square

(7.4) *Let G, G_1 be biladders, where $|V(G_1)| = |V(G)| + 4$ and $|V(G)| \notin \{10, 20\}$, and let G_2 be a handle expansion of G_1 . Then there exist a handle expansion G' of G and a homeomorphic embedding $G' \hookrightarrow G_2$.*

Proof. Let us assume that the vertices of G_1 are numbered $u_0, u_1, \dots, u_{p+1}, v_0, v_1, \dots, v_{p-1}$, as in the definition of biladder. The edges of the form $u_i v_i$ will be called *rungs*. Let us say that two edges e, f in a graph are *diverse* if they share no end and no end of e is adjacent to an end of f . It follows by inspection that if e, f are two diverse edges of G_1 , then there exist two consecutive rungs such that they are not equal to e, f and upon the deletion of the rungs and suppression of the resulting degree two vertices the edges (corresponding to) e, f remain diverse in the smaller biladder. Since deleting two consecutive rungs and suppressing the resulting degree two vertices produces a graph isomorphic to G , we deduce that the theorem holds. \square

The following variation of (7.4) is easy to see.

(7.5) *Let G, G_1 be biladders, where $|V(G_1)| = |V(G)| + 4$, and let G_2 be a circuit expansion of G_1 . Then there exist a circuit expansion G' of G and a homeomorphic embedding $\eta' : G' \hookrightarrow G_2$.*

The following theorem implies (1.3) and (1.4).

(7.6) *Let G, H be non-isomorphic cyclically 5-connected cubic graphs, assume that H topologically contains G , and assume that not both G, H are biladders. Assume further that if G is isomorphic to the Petersen graph, then H does not topologically contain the biladder on 14 vertices, and if G is isomorphic to the Dodecahedron, then H does not topologically contain the biladder on 24 vertices. Then there exist a cyclically 5-connected cubic graph G' and a homeomorphic embedding $G' \hookrightarrow H$ such that G' is either a handle or circuit expansion of G . Moreover, if H is dodecahedrally connected, then G' can be chosen to be a handle expansion.*

Proof. We proceed by induction on $|V(H)| - |V(G)|$. Let G, H be as stated, and assume that the theorem holds for all pairs G', H' with $|V(H')| - |V(G')| < |V(H)| - |V(G)|$. By (6.2) there exist a cyclically 5-connected cubic graph G_1 and a homeomorphic embedding $G_1 \hookrightarrow H$ such that G_1 is a 1- or 2-extension or a circuit expansion of G . If H is dodecahedrally connected, then by (6.1) G_1 can be chosen to be a 1- or 2-extension of G . We may assume that G_1 is a 2-extension of G , for otherwise the conclusion of the theorem is satisfied. From (7.3) we deduce that either the conclusion of the theorem is satisfied, or both G, G_1 are biladders, and so we may assume the latter. Thus $|V(G)| \neq 20$ by the hypothesis of the theorem. By the induction hypothesis applied to the pair G_1, H we deduce that there exist a handle or circuit expansion G_2 of G_1 and a homeomorphic embedding $G_2 \hookrightarrow H$. Moreover, if H is dodecahedrally connected, G_2 can be chosen to be a handle expansion. By (7.4) and (7.5) there exist a handle or circuit expansion G' of G and a homeomorphic embedding $\eta' : G' \hookrightarrow H$. Moreover, if H is dodecahedrally connected, then G' is a handle expansion. Thus the pair G', η' satisfies the conclusion of the theorem. \square

ACKNOWLEDGEMENT

We thank Daniel P. Sanders for carefully reading the manuscript, and for providing helpful comments.
